

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Instructions
IN
CLINICAL MEDICINE,

Given at the London Hospital by

SIR ANDREW CLARK, BART., M.D., LL.D., F.R.S.

(*Reported for* THE LANCET *and Revised by the Author.*)

INTRODUCTORY: THE METHODS OF CLINICAL INSTRUCTION.

GENTLEMEN,—I am much touched by and very grateful to you for this cordial reception. May I be enabled to continue worthy of your confidence. I enjoy to-day a great and valued privilege. Until now this hospital had no proper clinical theatre, and clinical instructions, which, next to the treatment of the sick, constitute one of the main duties of such an institution, were given in odd corners as convenience and other circumstances permitted. To-day, however, the new theatre is opened, and the privilege which I enjoy is the privilege of inaugurating the courses of clinical instruction hereafter to be given therein. We begin here and now the course of what is conventionally called clinical medicine. What is clinical medicine? It is that department of medical knowledge which occupies itself with the study of individual cases of disease as distinguished from that other department of medicine which occupies itself with the study of disease in general. It is that part of medicine which guides you to the investigation and discovery of the symptoms and signs of disease, to the classification of their relations, to the interpretation of their meaning, and to the elucidation of their bearing upon the general system and upon the course of the disease of which they are indications. It is that part of medicine which enables you to determine the nature of the particular disease with which you are dealing, to predict its course, to forecast its issues, and to determine the means most suitable for averting death, relieving suffering, or bringing about a cure. Such, briefly and imperfectly stated, are the objects of clinical medicine. It is for the sake of clinical medicine that all your previous studies have been undertaken. It is for the sake of becoming practitioners that you have studied physics, chemistry, anatomy, physiology, therapeutics, and pathology. For all these branches of knowledge supply information absolutely essential to the accurate and adequate conduct of clinical inquiry. Let me illustrate this, in passing, by reference to the secretion of urine. We have in clinical investigation to deal, as I was saying to you, with symptoms of disorder and of disease. Now, no single symptom exists in complete isolation; every symptom holds with other symptoms and conditions numerous varied and intimate relations. The secretion of urine is not, then, a solitary, simple, unrelated fact. And when we require to understand fully and rightly the influences at work in its production we have to search into the conditions of digestion, assimilation, the circulation of the blood, the variations of blood-pressure, the dynamic and structural conditions of the kidneys, and the state and action of the nervous system presiding over all. And when healthy urine becomes diseased urine, the clinical inquirer is compelled to investigate the condition of each of those factors in the evolution of the secretion of healthy urine, in order that he may discover to what alteration of what factors such diseased condition is due. Here you will discover the necessity of those branches of knowledge in the acquisition of which you have been hitherto engaged; here you will discover that physiology, a knowledge of the conditions of healthy structure and action, is one of the main foundations of the art of medicine; and here you will also discover that the very knowledge which enables you to inquire into and understand the nature of disease is in itself a constituent of the disease which you are striving to discover. Clinical medicine, then, is at once the object and end of all your previous studies; it is in a sense the closing and the crowning of all your former work, and it is the means whereby you are to make yourselves sound and true practitioners in the art and craft of medicine.

The study of clinical medicine is the most difficult of all the other studies in which you have been hitherto engaged, for it requires the possession of many different kinds of knowledge; and to use them aright it requires, furthermore, the careful exercise, not only of the higher mental, but also of the higher moral faculties of our nature; and no one can have any just hope of becoming practised in clinical medicine who does not devote himself patiently and perseveringly to the study of it. There are two other conditions which are above all others necessary to the success of this work: the one is that the attention which you give to it shall be undivided, and the other is that it shall be thorough. When you are engaged in the work of clinical medicine it is not tolerable that you shall be concurrently engaged in cramming for examinations upon other subjects. Clinical medicine is a jealous goddess, and never grants her highest favours to a divided worship. Furthermore, remember that your methods of working now will determine with unalterable certainty what your work and character and life are to be hereafter. Do not commit yourself to many cases at a time, for doing that will bring about superficiality, inaccuracy, and a loss of that calm seriousness without which just and wise judgments are impossible. In this study, before all other studies, it is required that you shall be thorough. Practise thoroughness now, and it will soon become a habit, and the habit of thoroughness will make for you the trustiest mental and moral gymnastic; it will develop your other faculties, it will elevate and strengthen your whole nature, and it will keep you in the way of rendering the highest service to men and of giving the truest help to the advancement of knowledge.

There are several methods of teaching clinical medicine. In one method the teacher prepares a lecture on a particular disease, giving his views of its nature, embodying his experience of its treatment, and selecting his illustrations from successive or concurrent cases in the wards. In a second method, the teacher, with the help of his house physician and clerks, prepares the case of a particular patient, determines the diagnosis, settles the treatment, and, assembling his students, reads to them the complete account of his investigation. In a third method the teacher collects his students round the bedside of the patient, listens to the story of the case, examines and compares the symptoms and signs of disease, considers and determines the diagnosis, forecasts the issues, and gives his reasons for the treatment which he proposes to pursue. From time to time the case is re-examined, the course which it has followed is discussed, and the treatment is revised. If death puts an end to the case, the results of the necropsy are considered in their relations to the assemblage and progression of symptoms which have constituted the external manifestations of the disease. In a fourth method the teacher endeavours to make the conditions of teaching resemble as nearly as is practicable the conditions of practice encountered by the medical man on commencing the practice of his art. Nothing is known beforehand of the patient to be examined. He is brought into the theatre, and the teacher, with the assistance of his students, proceeds to investigate the case, just as if the patient were a private patient, and the doctor were alone in the management of it. The symptoms and signs of disease are elicited, their relations and meaning are discussed, the diagnosis is considered and made, the prognosis is weighed, the treatment to be pursued is settled, and the report to be given to the patient and his friends is arranged.

The two first methods convey information, and, as usually practised, the information is of the highest character and conveyed in the ablest manner. But neither of them conveys a true instruction; neither of them constitutes a method of true education; both have grave defects, and one of the chief defects is that they do not make you think. The criterion of true instruction is not acquiring, but thinking. Genuine clinical teaching cannot be conducted through the medium of mere books and lectures: it requires the active co-operation of teacher and of taught, the assimilation as well as the acquisition of knowledge; seeing, handling, doing, as well as trying, failing, and succeeding. The third method, supplemented in the lecture room by retrospects and revisions, has the fewest defects and the greatest advantages, and is, on the whole, the most suitable for the conveyance of practical instruction in the art of medicine. Nevertheless, this is not the method which I purpose following in the present course of clinical instruction. I purpose following the fourth method, be-

Digitized by Google

cause it will afford us greater freedom of investigation; it will assimilate our conditions of work more closely than any other method will do to those methods under which the doctor, just qualified, will commence his practice; and it will be better adapted for the class of cases with which I wish to make you practically acquainted. There are three classes of cases to be met with in our hospital: the class of acute diseases, the class of chronic diseases, and the class of what I must be still permitted to call functional disorders.

For the study of cases of acute disease and of the graver forms of chronic disease adequate and admirable provision is made. But for the study of the slighter forms of chronic disease the provision made is inadequate, and for the study of that great variety of functional disorders growing with our advancing civilisation there is, beyond the necessarily incomplete instruction given in the out-patient department, substantially no provision made at all.[1] And yet, gentlemen, in carrying on your future work those cases of functional disorder are, probably, with few reserves, the most interesting, the most instructive, and the most important of all the cases with which you will have to deal. The study of those cases will make you familiar with the first results of the violations of physiological conditions and the earliest aspects of diseased states; they will make you familiar with them before temporary dynamical disturbances have drifted into permanent statical disease; and they will make you familiar with them when, as yet, the readjustment of diet and regimen, the judicious administration of drugs, and the regulation of all the little things of life which concur to make or unmake health, will enable you to restore the patient to health. Furthermore, cases of functional disorder and of the slighter forms of chronic disease will constitute the main body of the cases with which you will have to deal in practice; and your mastery of their forms and your skill in handling them will prove at once the measure of your usefulness and the criterion of your success. Among the functional disorders of which I am speaking there is one variety which in a special manner claims your closest study. It comprehends cases which abound in the present day, which are increasing with our advancing civilisation, which appear to arise out of irregular excitement of the nervous system, or out of neglect of the commoner conditions of healthy life, which are manifested mainly in an intense physical self-consciousness; cases which are the plague of families, profitable to the unprincipled quack, and perilous to every honest doctor. In this group of cases are the people who are always ailing and seldom ill; who, said to be sufferers from nervous debility, are yet capable of immense nervous work; who are not amenable to the curative effects of drugs; who are made worse by almost every remedy you propose; who often seek relief from stimulants and narcotics, who generally discredit your treatment, and who, nevertheless, when you fully understand their disorders and gain their confidence, are capable of being guided into that way of physiological righteousness which, despite their nervous troubles, leads them into useful, enjoyable, and worthy lives. I shall endeavour to bring cases of this sort before you; for even if the knowledge of them should not enable you to treat them successfully, it will enable you to escape discredit, and perhaps disaster, at their hands.

You will have already inferred from what I have said the mode of procedure which I purpose pursuing in the practical studies upon which we are about to enter. Nevertheless, for the sake of clearness and comprehension, it will be necessary to describe it in detail. But before I do this let me make plain to you the exact object which I have in view, that you may be neither disappointed with the nature of the instruction to be given nor dissatisfied with the limits within which it will be confined. Now my object is not the delivery of didactic lectures, not the reading of clinical essays, not the demonstration of technical proceedings, and not the discussion of rival pathological theories. All these procedures have their place and use. My one object now is to help you to get plain, practical clinical instruction, and so to get it of such a kind that you may pass from this hospital into practice accustomed to its methods and cautions, without fear of disaster, and ready for sound and honest work. At each meeting of our class, of which I expect all of you to become, in some way or another, coöperative members, my friend Dr. Hadley will present us a case for investigation, diagnosis, and treatment. Of the nature of this case we shall know nothing beforehand; and we shall proceed to deal with it in a manner resembling, as nearly as the widely differing conditions will permit, the manner in which you would deal with a like case in private practice. Of course the conditions in the two cases will be vastly different. There will be many persons present at the examination instead of one person, the tranquillity of the patient will be variously disturbed, we shall have to think and speak aloud, we shall have to discuss each other's procedures and conclusions, and teacher and taught alike may fall separately or conjointly into grave mistakes; but for all that the cardinal conditions of clinical work will be sufficiently alike to train you thoroughly, and initiate you successfully, into the practice of our art.

In dealing with each patient as he comes into the theatre it will be necessary to follow a definite plan of procedure. It may not be the best plan, and it may have many defects; but if uniformly acted upon and always employed as the standard of comparison and of judgment the results will be accurate enough for every purpose of our inquiry. In the first place, then, I shall ask the patient to tell us the symptoms of which he complains, how long he has been ill, and in what way his illness began. In the second place, I shall endeavour to learn from the patient the number and nature of the troubles from which he has suffered in the course of his life; for the continuity of organisms is one of the most instructive of teachers. In the third place, I shall make myself acquainted as closely and accurately as I am able with the medical history of the patient's family. In the disease of the parents we may sometimes read the diagnosis of an obscure disease in the child. Armed with information acquired from these sources, and assuming that the patient's statement points to the lungs as the chief seat of his malady, I shall proceed to investigate, with all modern aids to diagnosis, the condition of those organs. Completing this part of the examination I shall then inquire, through separate and successive investigations, into the conditions of the circulatory, digestive, genito-urinary, cutaneous, and nervous systems; and I shall ascertain the manner and degree in which the constitution is being affected by the disorders or diseases which we may have brought to light. At this stage of our investigation I shall be able to state in order the symptoms and signs of the patient's disease, and the signs and symptoms of disorder or of disease which may exist causally or independently elsewhere than in the lungs. I shall be able to elicit their relations, to interpret their meaning, and to set forth their bearing upon the future course and complications of the case. Now we shall be in a position to discuss the probable nature of the malady and to frame our diagnosis. This done, we shall consider the probable future of the case, settle the report to be made to the friends, and finally determine the treatment to be pursued. From time to time we shall re-examine the patient in order to correct or confirm our diagnosis, to determine the way in which the disease is going, and to consider the use or uselessness of our remedies.

Such, gentlemen, is the plan which, upon physiological lines, I intend to pursue in the conduct of these *clinical instructions*: and I feel myself justified in assuring you that if you adopt it in a spirit of serious endeavour, if you follow it step by step, if you pursue it unintermittingly, and if you bring all your collateral knowledge to bear upon its development, you will be preserved from confusion in emergencies, you will acquire a growing interest in your work, a precious habit will be formed in your mind, your whole nature will be lifted up, and in due season the fruits of your labour will be found abundant and good. Furthermore, the carrying on of your work in this manner will train your understandings, discipline your hearts, and exercise your wills to the utmost of their capacities; it will make you "cultivated men, it will enable you, on subjects of mutual concern, to hold your own with the public in the gate, and it will prepare you to deal successfully with those problems of the moral life from which few cases of disease are entirely exempt. Undoubtedly, my dear students, the fulfilment of these conditions will not be found easy. I am well aware, indeed, that it will be found tedious, disagreeable, difficult; and that it will exact self-denials always pressing, and efforts seldom slight. But then, I make the confident reply that it is only through the ready acceptance of these difficulties and sacrifices that you can acquire the strength necessary

[1] See Dr. Glover's admirable remarks on this subject, "Gaps in Medical Education."

Digitized by Google

for the work which you have hereafter to do. When the conditions of work and life become unencumbered and easy, failure is at hand and decay inevitable. It is a sacred and happy law which has made all good things difficult; it is only by the encountering and overcoming of difficulties that our mental and moral strength is developed and sustained; and it is only by the exercise and maintenance of this strength that we can reach and live that life of labour and of sacrifice which the doctor so often lives, and which moralists agree to regard as life indeed.

In conclusion, permit me to say a word or two on another but still closely related topic. I cannot pretend that anything has ever occurred to render necessary the speaking of these words to students of the London Hospital; and yet for many reasons, at this moment unnecessary and inconvenient to be specified, I may not leave them unspoken. The men and women who come into this theatre and submit themselves to be cross-questioned and in various ways examined before us have to pass through a considerable ordeal and to undergo some suffering. For they are our brethren; they have acute susceptibilities easily wounded; they feel deeply any slight or reflection which they imagine to be cast upon them; they are suspicious and ready to misinterpret; and any unfavourable judgment of their prospects of recovery, unwittingly expressed, fills them with apprehension and prevents their return for further examination. It is therefore necessary, and our duty, when patients are before us during examination, that all of us, you and I, should keep their presence in mind, and should abstain from any gesture or manner, from any look or word calculated to ruffle the temper or to wound the feelings of those who are voluntarily submitting themselves to both inconvenience and suffering for our common behoof.

An Address

ON THE

METHOD OF ZADIG IN MEDICINE,

Delivered at the Inaugural Meeting of the North London Medico-Chirurgical Society, on Thursday, Dec. 17th, 1891,

BY T. LAUDER BRUNTON, M.D., D.SC. EDIN., LL.D. (HON.) ABERD., F.R.C.P., F.R.S.

MR. PRESIDENT AND GENTLEMEN,—Allow me, first of all, to thank you for the great honour you have done me in asking me to address you to-night. The choice of a subject has not been easy, and, in trying to select one, it occurred to me that perhaps no animal gets to its goal more quickly or more surely than the carrier pigeon; yet, when started on its homeward journey, it does not fly directly onwards, but first of all takes two or three preliminary circles, in order to ascertain its whereabouts and the direction in which to direct its flight. The time spent in doing this is very far from lost, and what occurs in the case of the carrier pigeon appears to happen also in the conduct of human affairs. A little while ago I was down in the country, and a nurseryman, a most intelligent and able man, gave me a few lessons on pruning. He told me first of all what to avoid, and then what to do. "Some people," he said, "when they want to prune a tree begin with the knife at once, and cut here and there, without having a definite idea of what they are to do. Now the proper way is to put your hands in your pockets, stand a little distance off, look at your tree, see what you want to do, and then set to work." In laboratory researches we find the same thing, and a few preliminary experiments are often very advantageous in learning the methods of work, so that an apparent loss of time at the beginning is often a real saving both of time and trouble in the end. Now, as this is a new Society, it seemed to me that perhaps it might be better, instead of beginning with a definite medical subject, such as the pathology and treatment of some disease, to ask you rather to direct your thoughts to some general methods of investigation. Now one of the greatest losses in medicine is the loss of individual experience. We find that men most able and successful in the practice of their profession, in the recognition and treatment of disease, die and carry their knowledge away with them. Some men may record the cases they have seen, but comparatively few are able to record their experience in such a way as to make it thoroughly available for others. Various attempts have been made at different times to collect the experiences of medical men, especially those in general practice, and to put it in such a form as to be available for their colleagues.

In the years 1874-77,[1] in my capacity of editor of the *Practitioner*, I made an attempt to collect the experiences of practitioners by issuing a circular and asking for returns regarding the treatment of quinsy and sciatica. Answers were returned from all parts of the world, and these were collated and published. The advantage which was thus gained, however, seemed hardly enough to repay the time, trouble, and expense which these questions and returns necessitated, and the attempt was discontinued. A few years later another attempt was made on a very much larger scale by the Collective Investigation Committee of the British Medical Association, but after this had been continued for awhile it was also dropped. The same desire for the collection of information is shown, however, in the union of medical men to form societies in which everyone shall profit by the experience of his neighbour. The formation of the present Society is another indication of the value of this form of collective investigation, and it seems to me rather important that at its commencement we should pause a while and take a glance round before proceeding with what one may term its proper work, the consideration of diseases and their treatment. The failure of collective investigation to bring out any great amount of information from the profession as a whole shows that the task is no easy one; and if I fail to trace out for you a complete course by which our end may be attained you will not, I am sure, blame me, but will rather sympathise with my attempt, and will each and all of you endeavour to carry out further than I may be able to do the search for such methods as will enable us to attain the end we all desire. It seems to me that one cause of failure is a want of exact analysis, which leads to a want of exact synthesis. I may illustrate this by the common observation that, when we wish to describe the face of someone, all we are able to recollect, or at least to put into words, are the general facts that the individual has two eyes, a nose, and a mouth, with hair of a more or less pronounced colour. If we try to describe him more accurately, we may possibly recollect that his eyes are sleepy or bright, that his face is stout or thin, that his nose is long or short, that his chin is projecting or not. But here most of us would have exhausted our stock of reminiscences. Now, it is frequently very important that a face should be so exactly described that the owner of it may be at once recognised, and for this purpose a plan has been adopted in France of photographing the front face and the profile. The enormous number of photographs which are thus accumulated, of criminals and others in whom the officers of the law take an interest, is so great that it would be impossible either to pitch upon the particular photograph that was wanted or to recognise the individual if it were not for a system of arrangement. All profiles may be at once divided into three classes, according as the base line of the nose is ascending, horizontal, or drooping—and each of these may be further subdivided according as the bridge is convex, straight, or concave. When to these are added similar subdivisions, according to the shape of the eye and the ear, we see at once that the whole of the photographs may be readily classified, and any individual one that is wanted may be picked out from amongst thousands of others at a moment's notice. Many people remember faces sufficiently well to recognise them when they see them again, but not to describe them, much less draw a portrait from memory; yet it is by teaching the law officers to describe portraits from memory that they are trained to recognise from the photographs the people who may be "wanted." It appears to me that one of the kinds of training that is needed by medical men is this power of learning to differentiate the characteristics of a patient, the symptoms he presents, and the effects of treatment upon him in such a way as to render any case presenting similar features readily recognisable by a fellow practitioner. But it is not only the outward signs that we

[1] Practitioner, Nov. 1874, vol. xiii., p. 308; vol. xvi., p. 44; vol. xviii., p. 107.

Digitized by Google

have to differentiate in this way. We are obliged in medicine to judge of the unseen from the seen, and from the objective data which are presented to our senses we must draw conclusions regarding the processes which are going on, or have already gone on, in the persons of our patients. We must, in fact, track symptoms which we see back to their causes. Now this process of "tracking" appears to me to be a fundamental one in man, and one which seems really to be a remnant of the qualities possessed by our pre-historic ancestors. According to Haeckel, man runs through in his embryonic condition the history of the development of the race from a simple unicellular organism up to the human being. But even after birth traces of simian ancestry still appear. We have all noticed that when an infant is warming its feet before a fire the soles are not held straight forwards like those of an adult, but are turned in towards one another, and the great toes are drawn apart from the others in very much the same position as the feet of a monkey. Lately, too, Dr. Louis Robinson has shown that the arms of infants have an extraordinary power of supporting the weight of the body, and in this characteristic also an infant resembles the monkey. Even in adult life the position of the feet which we notice so easily in infants is retained by many, and we often find that the soles of people's boots are worn more on the outer than on the inner edge, the feet still tending to turn inwards, though only to a slight extent. The same tendency to reversion which we notice in the feet may be observed, I think, also in the faculties of the mind; and the keen interest in tracking game by which prehistoric man was enabled to exist still evidences itself in the intense eagerness with which boys will read in Cooper's novels about Indians in following a trail, or adults will pore over Gaboriau's stories of the police on the track of a criminal. There can be little doubt, I think, that the profession of medicine is a most intensely interesting one, and I am inclined to think that its special charm is, to some extent at least, due to the fact that it is constantly demanding the exercise of those qualities of tracking which we find in Cooper's Indian heroes. I know of no better example of the exercise of those faculties than that narrated by Voltaire in his story of Zadig. I thought it was an original idea of my own to point out the application of this method to medicine, but I find that I am only a humble follower of Professor Huxley, who has already written upon the applications of the method of Zadig to biology and palæontology [2]

Zadig was a young man who, disgusted with life, retired from Babylon to a lonely place on the banks of the Euphrates, and there studied animals and plants until he saw a thousand differences where others could only see uniformity. One day one of the Queen's eunuchs, followed by a band of officials, came hastening past and asked Zadig: "Have you seen the Queen's dog?" Zadig modestly answered, "A bitch, I think: not a dog." "Quite right," said the eunuch; and Zadig continued, "A very small spaniel, has lately had puppies, limps with the left fore foot, and has very long ears." "You have seen her, then," said the eunuch. "No," said Zadig, "I have never seen her, and did not even know that the Queen had a dog at all." At the same time the finest horse in the King's stables ran away, and the chief huntsman, when seeking it, also made inquiries of Zadig, who said: "A first-rate galloper, five feet high, small hoofed, tail three feet and a half long, cheek-pieces of the bit are of twenty-three-carat gold and the shoes silver." "Where is he?" cried the chief huntsman. "I have not seen him and never heard of him before," said Zadig. Naturally enough he was suspected of having stolen both the spaniel and the horse, and was tried and condemned; but no sooner was sentence pronounced than both the missing animals were found. Zadig was then asked to explain how he knew so much about them without having seen them, and this, he said, was the way. He noticed one day in the sand the tracks of an animal, which he easily recognised as those of a small dog. Long faint streaks on the ridges of sand between the footprints indicated that it was a bitch with pendent dugs, showing that she had had puppies shortly before. Other marks on the surface of the sand close to the prints of the forefeet indicated that she had very long ears, and one of the footprints being fainter than the others showed that she was slightly lame. As for the horse, the marks of his hoofs were all equi-distant, showing that he was a famous galloper. In a narrow alley the dust on the trunks of the trees was disturbed at three feet and a half from the middle of the path. This showed the length of his tail, which had swept the trees as he lashed it from side to side. Branches of the trees met overhead at a height of five feet, and under them were some newly fallen leaves, showing that the horse had brushed against them, and was therefore five feet high. As to his bit, he had rubbed it against a stone, which Zadig recognised as a touchstone, and his shoes had left such marks on the pebbles of another kind as showed they were made of fine silver.

A story very like that of Zadig's is told of an old fakir in the Syrian desert. He was one day visited by several Arabs, who asked him whether he had seen their lost camel. "It was very tall," said the fakir, "it was blind of the right eye, it had lost one of its front teeth, and it was laden on the one side with honey and on the other with corn." "Yes," said the Arabs, "that is exactly the camel; you have mentioned every point about it. Where is it?" "I have never seen your camel," said the fakir. "But if you have not seen it," said the Arabs, "how can you know all about it?" "I knew that it was a very tall camel because the tracks of its steps in the sand were further apart than those of an ordinary-sized camel. I knew it was blind of the right eye because it had cropped the herbage only on its left side, and I knew that it had lost one of its front teeth because in the middle of every bite that it had taken there was a small uncut part corresponding to where the tooth ought to have been. I knew that it had been loaded with honey on the one side and with corn on the other because I saw flies buzzing round one side of the track and ants busy on the other carrying away grains of corn that had fallen from the load."

An admirable example of the application to medicine of this method of tracking used to be told with great gusto by my late friend, Dr. Milner Fothergill, and I regret greatly that I cannot tell it with the same power and vividness that he did. In the town of Leeds there once lived a quack who had received no professional instruction whatever, but was known far and wide for his wonderful cures, and especially for his power of diagnosing the diseases of patients whom he had never seen, by simply examining their urine. A celebrated surgeon, Mr. X——, wishing to see his method of working, desired to be presented one day, and the quack readily acceded to his request, feeling much flattered that so great a man should patronise him. Shortly after Mr. X—— had taken his seat a woman came in with a bottle of urine, which she handed to the quack. He looked at her, then at the bottle, held it up between him and the light, shook it, and said: "Your husband's?" "Yes, sir." "He is a good deal older than you." "Yes, sir." "He is a tailor?" "Yes, sir." "He lives at Scarcroft?" "Yes, sir." "His bowels are obstinate?" "Yes, sir." "Here," he said, handing her a box of pills, "tell him to take one of these pills every night for a week, and a big drink of cold water every morning, and he will soon be all right." No sooner had the woman gone out than Mr. X—— turned to the quack, curious to know how he had made out all this. "Well, you see," said the quack, "she was a young woman, and looked well and strong, and I guessed the water was not hers. As I saw she had a wedding ring on her finger, I knew she was married, and I thought the chances were it was her husband's water. If he had been about the same age as she it was hardly likely that he was going to be ill either, so I guessed he was older. I knew he was a tailor because the bottle was not stopped with a cork, but with a bit of paper rolled up and tied round with a thread in a way that no one but a tailor could have done it. Tailors get no exercise, and consequently they are all very apt to be constipated. I was quite sure that he would be no exception to the rule, and so I gave him opening pills." "But how did you know she came from Scarcroft?" "Oh, Mr. X——, have you lived so long in Leeds and you don't know the colour of Scarcroft clay? It was the first thing I saw on her boots the moment she came in."

Now, of late years we have got so many new methods of investigation that we are sometimes apt to forget the old habits of close observation by which this quack made out so much, and proved himself, although without any diploma, a worthy descendant of the water doctor whose picture by Gerard Dow occupies such a distinguished place in the gallery of the Louvre. Without resorting to the plan of

[2] On the Method of Zadig. Nineteenth Century, 1880. Reprinted in Science and Culture.

Digitized by Google

testing the urine, by which that water doctor and his brethren of the craft no doubt recognised the presence of sugar, he could learn a great deal from its simple appearance.

Some years ago, when staying in the country with a medical friend whose wife was boiling some eggs in the dining-room for breakfast, I said to her from the other side of the room, "You have cracked one of those eggs now." She said, "I don't think I have." On taking them out of the pan, however, she found that one of them was cracked. She wondered how I knew, but the explanation was simple enough. The pan had boiled over, the water would not have held the steam long enough to boil over, unless there had been something in it to make the bubbles tenacious, and this could hardly be anything else but albumen which had escaped from a crack. In the same way, although the water doctor did not know about albumen, he probably recognised that the persistence of froth on the urine after shaking it was of somewhat ominous import, and that would lead him to give a guarded prognosis, just as one nowadays sometimes pities an old gentleman who unconsciously proclaims his precarious tenure of life by the froth he leaves behind him in the public urinal.

The water doctor may even have learned to associate this frothiness with nervous symptoms, such as restlessness, irritability of temper, and sudden outbursts of passion quite out of proportion to the amount of offence. I well remember an incident some fifteen years ago where an apparently causeless outburst of fury on the part of an ordinarily quiet man completely astonished all his friends, who only understood it when his subsequent illness and death showed that his sudden passion was but an indication of unsuspected disease. The steward of St. Bartholomew's Hospital, Mr. Mark Morris, a man of very keen observation, has told me that whenever a patient comes down to the office at 11 o'clock at night and wants to be discharged there and then, they know that he is suffering from cardiac disease. Perhaps the outburst of fury in the Emperor Theodosius,[3] which resulted in the massacre of Thessalonica, was only an indication of the disease which later on resulted in dropsy and death. The water doctor would be sure to divide his frothy urines into pale and dark, and he would know that these two corresponded to quite different types. The dark urine was probably passed by an individual who was short of breath, disposed to rest, and frequently drowsy. The pale urine would be passed either by an individual who rose in the morning with his eyelids swollen and puffy, and who was probably drooping and languid during the day, or by a person of quite a different stamp, energetic, irritable, restless, sleepless, always on the move, and driving on like a high-pressure engine. Further than that, perhaps, the water doctor might not go, but we know now that the dark, frothy urine has probably been passed by a man suffering from cardiac disease, while the pale urine is due to renal mischief; and the classical researches of Bright and others have shown us that the man with big eyelids has probably tubular nephritis, while one who drives himself and his neighbours without intermission suffers from contracting kidney. Nay more, physiological and pathological researches have taught us that the dark urine of cardiac disease is due to low tension in the arterial system in general and in the renal arteries in particular, so that the excretion of water is diminished, while the pale urine is due either to high tension in the arterial system, as in cases of gouty kidney, or to diminished power of excreting solids in chronic nephritis.

But there are other indications of disease which may sometimes be recognised without examining the urine, and I was greatly astonished by a man diagnosing albuminuria from the photograph of a patient, although there was no swelling whatever visible in the face. On inquiry afterwards I learned that the diagnosis was made from the glistening of the eye. A tendency to œdema had caused reflection of light along the sclerotic, and this caused the eye to appear more brilliant than usual. A similar glistening of the eye we get as an effect of the emotion of compassion, in which the increased secretion of tears moistens the eyeball more than usual. An entirely different effect is produced by the emotion of anger, where the eye does not glisten, but glitters, or by great grief, which renders the eyeball dull and lustreless. If we try to follow these appearances back to their physiological cause, we may find our attempt helped by considering a typical lack-lustre eye, such as that of a dead cod-fish. We see at once that the eyeball here is flaccid and its surface perhaps indented, instead of being tense, as it ought to be, and its surface smooth. We may imitate this condition very readily upon a child's indiarubber balloon. If we let the air out it at once becomes limp. If we blow it out it begins to shine, and the tighter we blow it the more does it reflect the light. The tension in the eyeball under ordinary conditions has a relation to the tension of the blood, and the bright eye indicates the stout heart which may win the fair lady, while the lack-lustre eye is associated with a feeble circulation, which frequently has its origin in the depressing emotions of sorrow or fear. The glittering which occurs in anger is, I think, part of the same physiological process by which the face in great anger becomes pale, and the blood becomes concentrated internally, ready to supply force to the muscles in a sudden attack upon the enemy. It has always seemed to me that Orchardson's wonderful picture of Voltaire complaining of the insult that had been offered to him would have been rendered still finer by a very minute touch of white upon the eyeball, to indicate the glitter of anger. The bright eye of consumption is familiar to us all, the high temperature so common in the disease tending to make the circulation more than usually rapid, the intellect often more keen, and the hopes more bright than in health, though the face may be emaciated and the body reduced almost to a skeleton. But if we find in a thin person a languid instead of a bright eye, we are led to look for the cause of the patient's leanness rather in want of food than in rapid combustion, and not unfrequently, if inquiry teaches us that the patient is able to obtain food, we may diagnose either that he cannot eat or cannot digest.

Now it does not do to make one's diagnosis too rapidly, for otherwise one may fall into grievous error. I remember once a whole class of students standing round a man with a loud cardiac murmur, and one of his pupils much dilated. After many learned opinions had been expressed regarding his case, the man informed us that the eye over which we had been having such an animated discussion was a glass one. A similar occurrence happened to a learned professor. He was telling his students that he was able to discover this, that, and the other thing from the appearance of his patient's teeth. The woman took them out, and said, "Please, sir, I will hand them round; they might like to look at them closer." Yet, in spite of these risks incidental to all hasty observation, the habit of close attention to minute detail which this professor tried to inculcate was a most useful one, and many of those who scoffed at him five-and-twenty years ago have learned to respect and admire him. The process of tracking disease to its cause will often help us greatly in treatment, for unless we can remove the cause all therapeutic measures may be useless. I remember on one occasion being consulted by a gentleman who was second in command in a department involving not only heavy work, but great worry. He was suffering from dyspepsia, and looked thin and worn. I examined him most carefully, and could find absolutely no cause for his symptoms. Knowing, however, the conditions under which he was working, I said to him, "How is your chief?" "He is not well." "Is he irritable?" "Yes, very." "Who is physicking him?" "Dr. So-and-so." I returned him his fee, and said, "Go to Dr. So-and-so and tell him to physic your chief; it is of no use for me to try to cure you with medicine." I met my patient some time afterwards, who, with a sly glance at his chief, whispered to me, "Your prescription was very efficacious."

One of the best examples that I know of tracing symptoms to their cause is afforded by Weir Mitchell's observations on chorea and on neuralgic pains. During the American War he took great interest in cases of gunshot wounds, and especially those involving injury to nerves. After the war was over his patients were scattered far and wide over the continent of America. He was struck by the curious coincidence in the reports which he got from them, and observed that one day (to put it roughly) he might get letters from San Francisco, saying that his patients in that district were suffering from pains in their scars; next day he might get a packet from the neighbourhood of Denver, next day from Chicago, and next day from New York. He thus noticed that a wave of pain was passing across the country. He next obtained the meteorological records, and found that a wave of rain was passing across the country at the same

[3] Gibbon's Decline and Fall of the Roman Empire, chap. xxvii.

Digitized by Google

time and with the same speed. By comparing the pain-area with the rain-area he noticed that the two were concentric, but that the pain-area had a much larger radius than the rain-area. Thus all the patients in the rain-area, when they felt twinges in their limbs, looking up at the sky, would say, "It is raining to-day, and that is the cause of my pains." But those in the part of the pain-area outside the rain-area, when they looked up, saw that the weather was fine, and could thus discover no cause for their sufferings, although these were due to meteorological disturbances just as much as those of their fellow-sufferers in the rain-area. The way in which Weir Mitchell showed the dependence of chorea on meteorological changes was almost as interesting as the relationship between pain and weather. He tabulated all the cases of chorea occurring in Philadelphia, and drew out a chart to show them diagrammatically. He then got the meteorological records and tried to find what conditions caused an increase in the cases of chorea. He tried the mean daily range of the thermometer, the average temperature, the average barometric pressure, the relative humidity of the air, but little or no correspondence could be traced between the curves representing these different factors and the curve of chorea. The curve showing the amount of rain and snow in inches showed a slight general resemblance to that of chorea, the curve showing the days on which the rain or snow fell came still nearer, but the curve showing the number of storm centres passing within 400 miles of Philadelphia showed a likeness to the curve of chorea which was very remarkable. In the same way he showed that the curve of infantile palsy closely corresponded with the curve of temperature, though not precisely so. We now constantly receive from America telegraphic information of the approach of storms, and we may well fancy that the day is not far distant when warnings will be published in the newspapers, not only to seamen of approaching storms, but to invalids and people in general of the meteorological changes which will induce pain in some and nervous excitability in others, with perhaps an added hint that extra flannel should be worn by the former, and bromide of potassium or some other nervine sedative taken freely by the latter.

One of the commonest observations in medicine is that cases come in a run. In hospital practice this is very striking. On one day you will see a great number of cases of bronchitis, another day cases of diarrhœa, another day cases of rheumatism, and so on. It has seemed to me, for a good many years back, that a most useful study would be the connexion between such runs of cases of disease and meteorological conditions. I may, perhaps, be allowed to suggest that such a society as the present might find this a useful branch of work, and one which would not entail a great deal of labour if it were properly done. Each week, or each fortnight perhaps, the members might jot down in one word the kind of cases of which they had seen most, and their individual notes might be classified, so as to give the general results, by some member chosen for the purpose. He would then be able readily to get the meteorological records, and by comparing these with the cases which had come in a run the relationship might be traced between the condition of the weather and the class of patients most affected. We are accustomed to warn patients suffering from pulmonary diseases, either phthisis or bronchitis, or from albuminuria, to avoid chills; but I do not think that the meteorological factors which give rise to exacerbation of symptoms in all these diseases have been at all satisfactorily determined as yet. The process of tracking might thus be advantageously followed, in regard to the external conditions giving rise to disease, by this Society, but the process ought not to end here; it ought to be followed onwards to the internal constitution of the patient. You will often hear people who do not believe much in doctors still say that they are unwilling to go to anyone else than the man who has attended them and their families for a long time, "because," they say, "he knows my constitution." If we try to analyse what they mean by this, I think we will find that "the constitution" implies the kind of reaction which occurs on the application of any external stimulus. Take three men belonging to different families, for example. Put them on the top of an omnibus and let them drive out on a rainy day, and with a cold wind blowing. One man comes home and has a bad bronchitis, the second an attack of sickness and diarrhœa, and the third gets an attack of rheumatic pains. The meteorological conditions to which each man has been exposed were the same, but the results have been quite different, the difference depending upon the constitutions of the individuals. But people belonging to different families do not only react differently to meteorological conditions or to other causes of disease, they are also differently affected by remedies. One of these three men, for example, might tolerate with impunity, and indeed derive benefit from, large doses of arsenic which would cause sickness and diarrhœa in another; while a second might get headache, deafness, and possibly a cutaneous rash from a quantity of quinine which would only produce a feeling of strength and well-being in another. It is the knowledge of the way in which different families will react to drugs that constitutes the most important part of the experience of an old practitioner, and which forms one of the greatest difficulties in the way of a medical man treating strangers satisfactorily and certainly. When a stranger comes before him presenting certain symptoms, he can only deal with the disease according to average rules, and yet this individual patient may present the exception to these rules, and consequently the treatment fails.

But it is not only in different families that we find drugs having a different action; different individuals in the same family will not react always in the same way, either to the cause of disease or to the mode of treatment. Nay more, a further complexity is introduced by the fact that the same person will react differently in youth, manhood, and age to causes of disease and to remedies. We not infrequently find, for example, that a youth who has been liable to bronchitis presents symptoms of dyspepsia in middle age, and may again have a pulmonary affection in old age. If these variations in families and individuals could be traced to their origin the benefit conferred on practical medicine would be immense. We should then be able to overcome satisfactorily one of the great difficulties which constantly meet us at the present time, and instead of simply *trying* our remedies, choosing first one and then another amongst those most likely to suit, we should then be able to select the drug most suited to any individual case with certainty, and treat the disease with success. In this attempt I think we may be greatly helped by the law of heredity. At present we acknowledge it to a certain extent. If a man's grandfather has been gouty we are not at all astonished at the reappearance of the gouty symptoms in the grandchild. If either the father or the mother has been consumptive we dread the same disease in their progeny: but if one child should resemble the consumptive mother and the other the hale and hearty father, we should use special care to guard against colds in the former, and have very much less fear of any tubercular tendency in the latter. We acknowledge, in fact, that the members of one family throw back to different ancestral strains either on the father's or the mother's side, and that they do this not only in external appearance, but in tendencies to disease, and this is still one of the points which wants close and careful investigation. The different tendencies of an individual in either childhood or age may be regarded as a kind of reversion to different ancestors at various periods of life. This has been beautifully put by Oliver Wendell Holmes in his novel "The Guardian Angel." The heroine of this story, Myrtle Hazard, runs away from home, and, floating down the river in a boat, sees at dusk, in an old Indian burying place, a curious vision. Around the burial mound various figures seem to flit, some thin and shadowy, others more substantial, but still misty; while others again appear almost as distinct as living men and women. She recognises, as one does in a dream, that these are her ancestors, the solid ones closely related to her in blood, while the thin and shadowy are far removed. Each ancestor has an existence in herself more or less definite according to the nearness or remoteness of blood. It is not necessary to trace our heroine through her various adventures; but at one time she develops suddenly and unexpectedly, under provocation, the characters of an Indian squaw from whom she is descended, and nearly slays a schoolfellow while they are acting together. Later on another ancestress, who was a famous beauty, appears in a dream, and for some time afterwards the heroine feels this beauty living within her and directing her actions; while later still another ancestress, who has been a great saint, drives the capricious beauty out and leads the heroine in the way she should go.

As I have already said, Haeckel believes that during intra-uterine life the fœtus rapidly runs through the

Digitized by Google

development of the race up to mankind, and I think we may in after life trace the progress of the individual through various ancestors more and more slowly as he advances in years. In infancy and childhood we frequently notice how rapidly the features change, and friends will say at one visit how like the child is to some member of his father's family, while a week or two after they will notice a resemblance to someone of his mother's family. If this Society can gather together notes as to whether an individual presenting an unwonted reaction to medicine happens to resemble at the time someone either of his father's or his mother's family who had a similar peculiarity, a great step might be made. This, however, is not all. We have next to try to trace why medicines act differently upon different families. It is just possible that this also is a case of reversion to a very far-off period; indeed, before mankind had even reached the level of the monkey. Some years ago it occurred to me that one might possibly gain some information regarding the peculiar differences in the action of drugs on gouty and other individuals by comparing the effects of certain poisons or remedies upon such animals as rabbits, which excrete their nitrogenous waste in the form of urea, and pigeons, which excrete it in the form of solid urates. Now Weir Mitchell had shown that pigeons had a singular power of resistance to the action of opium, and can take large quantities of it without presenting any symptoms of narcosis. Dr. Cash and I made some experiments upon the subject, and we found that opium in moderate doses appeared to have almost no action upon pigeons, yet on examining more closely we found that it had a very marked action, only it did not produce sopor, but caused the temperature to fall greatly. Instead of acting as a narcotic it acted as an antipyretic. We did not try the converse of this by giving antipyretics such as antipyrin to pigeons and seeing whether they acted as soporifics, but in patients we certainly do find that occasionally, as in acute inflammation, opium seems to have an antipyretic action, whereas antipyrin certainly acts at other times like a soporific. In order to track these actions further back still and find out what changes in the circulation, blood, nerve cells, and nerve fibres the action of these various drugs depends, a large amount of experimental work in laboratories is required.

Until lately there has been no opportunity for young men generally to do such work in this country, and those who wished to undertake it were obliged to go abroad. Now, however, owing to the wise action of the Colleges of Physicians and Surgeons, opportunities are being afforded for such investigations; but all such researches will give only one side of the subject, and will remain valueless unless clinical observation can be brought to bear at the same time on therapeutic studies. The members of this Society, by the fact that they have founded it, have shown their desire to forward the progress of medicine. I have to-night tried, in a very imperfect way indeed, to consider some of the methods by which I have thought their objects might be to some extent attained; and even if I should have failed to show you how to work, this evening may not have been uselessly spent if I have succeeded in directing your attention to the search after methods of attaining the objects which we all have at heart—that of securing health and ease to our patients with quickness and certainty.

AN INFECTIOUS DISEASE HOSPITAL FOR ST. ALBANS.—At a recent special meeting of the St. Albans City Council, it was announced that Mr. J. Blundell Maple, M.P., was willing to erect, on a site already selected, a hospital for infectious diseases, to be called the "Sisters' Hospital," at an expense of £6000, to be presented to the St. Albans Corporation on behalf of the city and neighbourhood. Mr. Maple has also promised to present a recreation ground and people's park to the city.

AYR COUNTY HOSPITAL.—The utility of this institution has been again exemplified by the extended area of the benefits it has bestowed during the past year. The hospital has been more taken advantage of than in any previous year of its existence, the marked feature being a greater number of cases from outlying districts. The total ordinary income and expenditure respectively during the year were £1728 1*s.* 8*d.* and £2169 4*s.* 4*d.*, showing a deficiency of £441 2*s.* 8*d.* The endowment fund now amounts to £5922 13*s.* 7*d.*

Clinical Lectures
ON
STRICTURE OF THE ŒSOPHAGUS,
WITH FOURTEEN ILLUSTRATIVE CASES, IN FOUR OF WHICH GASTROSTOMY WAS SUCCESSFULLY PERFORMED.[1]

BY DAVID NEWMAN, M.D.,
SURGEON TO THE DEPARTMENT FOR DISEASES OF THE THROAT AND NOSE AT THE ROYAL INFIRMARY, AND ASSISTANT SURGEON TO THE WESTERN INFIRMARY, GLASGOW.

LECTURE I.

GENTLEMEN,—Since the beginning of the present session you have had brought under your notice an unusually large number of cases illustrative of the class of disease which will occupy our attention in this and the succeeding two lectures. Diseases of the œsophagus leading to more or less complete stricture are not as a rule met with in considerable numbers even in our large hospitals, therefore it is the more remarkable that during the last three months you have seen so many cases in which the patients suffered from marked dysphagia as a consequence of disease of the gullet, or from pressure upon that canal. Most of these cases were sent to me by their medical attendants, while others came to the out-door department of their own accord, and simply complained of difficulty in swallowing, together with weakness, as a result of inability to take a proper amount of nourishment. In all the cases brought before you the most prominent symptom was difficulty or impossibility of swallowing food.

When we were studying the general symptomatology of diseases of the throat, your attention was directed to various conditions which may manifest themselves by difficulty or even impossibility in swallowing food. Hence various terms are employed to designate the character or degree of obstruction to the passage of food. When swallowing is painful, the patient is said to be suffering from odynphagia, as, for example, in inflammation of the œsophagus resulting from the action of corrosive agents. On the other hand, when the lesion is of a chronic character, such as cicatricial stricture or the pressure of tumours upon the gullet, the patient may suffer comparatively little pain, while the obstruction to swallowing is great. To this condition the term dysphagia is applied. Again, should the obstruction be complete, as in Cases 3, 4, and 7, the patient is said to be suffering from aphagia. Besides stricture of the gullet properly so called, the lesions which give rise to œsophageal dysphagia are numerous and varied; but as most of them will require to be referred to when we come to consider the question of diagnosis, I will simply enumerate them at present. Congenital malformations and the impaction of foreign bodies in the gullet very seldom give rise to much difficulty in diagnosis, but it is otherwise in those cases of aneurysm of the aorta, mediastinal tumour, enlarged lymphatic glands, exostosis or curvature of the spine, which, by pressure upon, or by causing distortion of, the œsophagus, may lead to serious difficulty in swallowing. The cases of aneurysm of the transverse arch of the aorta causing pressure on the gullet at the level of the bifurcation of the trachea are perhaps the most important.

Using the term "stricture of the œsophagus" in its proper sense, it may be divided into four varieties—viz., malignant stricture, obstruction by benign tumours, organic stricture, and spasmodic stricture. We will now consider these diseases in detail, and afterwards discuss the questions of prognosis and treatment. Two forms of malignant disease attack the œsophagus—the carcinomata, which are very common and usually occur as primary lesions, and the sarcomata, which are rarely met with in the gullet unless as secondary to sarcomatous formations in other parts. Carcinoma is by far the most important and also the most common new formation met with in the gullet; and it appears that any part of the tube may

[1] Selected from a course of lectures delivered during the winter session 1890–91 at the Royal Infirmary, Glasgow.

Digitized by Google

be attacked, although there are certain points which are more liable to the disease than others. Taking, for example, the seven cases of cancer of the œsophagus which have come under our notice this session, it was observed that in two the tumour occupied that portion of the œsophagus situated behind the larynx; in other two the stricture was found to be on a level with the bifurcation of the trachea, while in three the cancerous growth attacked the gullet at its lower extremity. There is considerable difference of opinion as to the most common situation of the primary disease. Some observers assert that the lower third is the most frequent seat,[2] while Mackenzie[3] and others assign 44 per cent. of cases to the upper third, and say that only 22 per cent. occupy the lower third.

As far as my own experience goes, it appears that the most common spot to find the primary growth, at least as far as can be discovered during life, is immediately behind the cricoid cartilage, and that the next point most liable to attack is at the level of the bifurcation of the trachea. Statistics derived from the inspection of pathological reports do not afford very reliable data; because in such instances the disease is not observed at its onset, but after it has terminated the life of the individual and extended far beyond its primary focus. Even in cases examined during the early stage of the disease it is difficult to ascertain the precise limits of the lesion: all we can learn is the highest point of obstruction, unless in those rare cases in which the œsophagoscope may be employed. From a clinical point of view, the most important fact is that carcinoma of the œsophagus very frequently is situated, and may cause obstruction, at the level of the bifurcation of the trachea—namely, at a part where the gullet is likely to be pressed upon by a mediastinal tumour, or by an aneurysm of the arch of the aorta. As a matter of interest, I have contrasted a number of tables drawn up to prove the part most liable to attack; but the discrepancy between them is so remarkable that the value of individual tables is by no means high. For practical purposes we must, however, consider carcinomatous disease in reference to the situation of the tumour. When situated high up and of small size, the tumour possibly may be removed by œsophagectomy, or œsophagostomy may be performed, while if large in size the neoplasm may cause obstruction to respiration and demand tracheotomy. Again, when the tumour is situated at the bifurcation of the trachea, great care must be taken in the employment of bougies, on account of the danger of causing injury to the trachea or aorta, and at the same time, before adopting any line of treatment, the possibility of the obstruction being due to an aneurysm must be eliminated.

We now come to consider the etiology of carcinoma of the gullet. We know just as much and as little regarding the causation of tumours in this situation as in other parts of the body. The two important predisposing causes are sex and age; we will leave out of account the question of heredity. Some observers, however, attach considerable importance to heredity as a cause of malignant disease, but to my mind the influence of inheritance in the production of malignant disease has not been proved, as it has been, for example, in such diseases as hæmophilia, Daltonism, and diabetes insipidus.

Age is a most important factor. Of 510 recorded cases, the ages of which I have ascertained, 80 per cent. were between the ages of forty and seventy years, 12 per cent. were below forty, and 8 per cent. above seventy. Again, on examining more carefully into those between the ages of forty and seventy, nearly a half (or 40 per cent. of the 510 cases) were found to be between forty-five and fifty-five years of age. In considering the influence of age it must always be remembered that each decennial period does not contain the same number of individuals; so that, to be quite accurate in our calculation, it would be necessary to estimate the percentages with the fact in view that each decennium as it advances contains fewer individuals.

Another circumstance which must have attracted your attention is that out of the seven cases shown to you only one was a woman. One in seven is, however, a little below the general average. Of the 510 cases referred to already, 108 were women and 407 were men, and of all the cases which have come under my own observation only 10 per cent. were women. For practical purposes it may be said that four-fifths of the cases of cancer of the œsophagus occur in males. In this particular epithelioma of the œsophagus resembles the same disease as it attacks the lip, the tongue, the larynx, and the rectum. But while these parts are more liable to be attacked by malignant disease in men, in women disease of the sexual organs is disproportionately frequent. No reasonable explanation has yet been offered for this peculiarity, and it remains as one of the many facts in regard to the etiology of cancer of which we know little.

Regarding the exciting causes of cancer of the œsophagus there is only one point worthy of attention—namely, that protracted slight irritation is likely to determine the site of the primary growth. This point has been well illustrated by cases shown, in which the points of selection were—(1) The upper part of the œsophagus, where the tube becomes suddenly narrowed behind the cricoid cartilage, and where during deglutition the bolus of food is moulded into form to pass down the gullet; (2) at the point where the œsophagus passes behind the bifurcation of the trachea; and (3) where it penetrates the diaphragm, in all of which situations there is more likely to be obstruction to the passage of large morsels of food. Again, it has been observed that epithelioma of the œsophagus may follow upon simple stenosis, or upon an old cicatrix, just as we may have malignant disease planted on an old syphilitic cicatrix on the tongue, or a burn of the skin.

In many of the cases which have come under my notice the patients have told me that for a considerable time, sometimes for years, before they experienced any difficulty in swallowing, they were troubled with "indigestion and acidity," and had been falling off in general health. In instances where these symptoms existed for only weeks or months, the possibility is that the malignant disease was present from the onset, but when symptoms of gastric and œsophageal irritation have been present for years previous to any definite obstruction to swallowing, one cannot but seek an etiological relationship between the chronic inflammatory lesion and the carcinomatous growth. Is it likely that the tumour in this case, as in the more acute cases, existed from the beginning of the illness?

Passing now to the consideration of the pathology of the carcinomata of the œsophagus, we have already seen that there are certain points of selection; but while this is so any part of the tube may be attacked. When the disease is, as is usually the case, a squamous-celled epithelioma, the histological structure and mode of growth closely resemble cancer of the lip or of the larynx. A small raised, warty, or nodular tumour appears. The proliferation of cells probably takes place, in the first instance, in the deeper layers of the mucous membrane, but very soon the basement membrane is perforated and the actively increasing epithelial elements infiltrate the underlying connective tissue. The tumour may remain isolated, but as a rule it assumes an annular appearance, and soon forms a distinct obstruction to swallowing. The disease may further extend into the muscular coat, and afterwards into the adjacent parts. The central or more prominent parts of the growth may now ulcerate, and, as a consequence, at this stage the impediment to swallowing may be somewhat relieved. If death occurs at this period a deep ulcerated ring will be seen to be overlapped by the elevated edges of the upper and lower portions of the tumour. In most instances the obstruction is not entirely due to the space occupied by the tumour proper, but is increased by inflammatory induration of the connective tissue. This inflammatory new formation, together with the granulation tissue of the ulcer, contracts as the disease advances: so that while the epithelioma is being destroyed by a destructive process the calibre of the gullet is soon after reduced by the contraction of cicatricial tissue. It is therefore commonly observed that, during a certain period in the course of the disease, marked improvement may occur in swallowing (as in Cases 4 and 7), while later on dysphagia becomes more marked than at any previous time.

When examined microscopically, the squamous-celled epithelioma is usually found to be of the infiltrating form. The epithelium is seen to infiltrate and destroy the submucous connective tissue by sending long processes and laminated capsules into the underlying tissue. These capsules are very characteristic of this form of epithelioma. In the aggregated form the cells take, on section, the appearance of globes, but individually they are arranged in a concentric form, like the coats of an onion. The growth is usually softer, and the connective tissue more abundant,

[3] Diseases of the Œsophagus, p. 88.

Digitized by Google

than is observed in epithelioma of the lip or of the skin. But while the squamous-celled carcinoma is the most common growth in the gullet, other varieties of cancer are met with.

CASE 1.—For example, three years ago a patient who was under my care died from starvation, with the most marked and complete obstruction at the lower end of the œsophagus, and at the post-mortem examination a tumour was found occupying the lower three inches. The new growth uniformly infiltrated the œsophageal wall, and both its lower and upper extremities were abrupt, and the parts below the cardiac orifice were free from disease, while the mucous membrane of the gullet above the tumour was the seat of only slight inflammatory changes. There was no ulceration at any part. On transverse section the tumour was seen to occupy the whole thickness of the wall, and measured from the mucous to the outermost limit about half an inch. The lumen of the tube was so reduced that even after death it would only admit a No. 3 urethral bougie. On microscopical examination the tumour was proved to be a cylindrical-celled epithelioma, or adeno-carcinoma, similar to what is usually met with in the rectum. It presented a distinctly glandular appearance in some parts; while in others, as a consequence of active cell multiplication, the adenoid structure was not strictly preserved, and the cylindrical form of the cells was lost, except perhaps in those forming the layer next the stroma. These aggregations of epithelial cells were of considerable size, and were separated from one another by a coarse alveolar stroma, partly composed of newly formed connective tissue and partly of dissected involuntary muscular fibres. This growth closely resembled in its structure and history the destructive adenoma of the stomach, large and small intestine, and rectum. These neoplasms start in the mucosa, but soon invade the deeper layers, and are accompanied by an inflammatory connective tissue proliferation, together with the development of a large number of neoplastic tubules. These first invade the submucosa, but very soon thereafter they extend, ultimately dissect their way between the muscular bundles, and may even extend to the serous covering of the alimentary canal. In the case now under consideration the patient was starved before the growth had time to extend into the neighbouring tissues or give rise to metastasis.

Mr. H. T. Butlin,[4] in his admirable monograph on Sarcoma and Carcinoma, refers to three cases of hard cancer or scirrhus of the gullet. He says: "The hard cancers are said to have presented a well-marked alveolar structure, and in one of them the mucous glands were thought to be the point of departure of the disease. The duration of the third case is not known, for the patient was too weak to communicate the hisory of his illness during the two days he was an inmate of the hospital before his death; but the duration in each of the first two cases was much longer than in the most prolonged of the cases of epithelioma. Even at the end of two years the second case does not seem to have completed its course, for neither the glands nor any of the organs were the seat of secondary growths. And in the first case, although the disease was believed, on what appeared to be sufficient grounds, to have existed for upwards of three years, only a few small nodules were found in the lungs and one small tumour in the liver, while the condition of the glands is not recorded." Three years ago I saw the last of a case very similar to the one just quoted.

CASE 2.—This patient, a man aged fifty-nine, consulted me for the first time on Nov. 1st, 1886—that is to say, about two years previous to his death, and nearly three years after the onset of the first symptoms of stricture. In other words, without the aid of an operation, the patient lived for five years with a scirrhous cancer of the œsophagus. The first symptom was difficulty in swallowing, which was observed by the patient in January, 1884. At first the dysphagia was so slight and transitory that he thought little of it, and he did not consult a medical man till November of the same year. At that time a No. 11 bougie could be passed, after which the patient experienced some relief, and he did not complain of pain, nor at any time was blood observed in the vomited matter, or in the expectoration. He could swallow fluids and semi-fluid food with ease, but frequently he had difficulty in taking such articles of diet as bread, potatoes, and meat. In the interval between Nov., 1884, and January, 1886, so far as I could learn, the symptoms, although varying in degree slightly from time to time, remained practically the same at the latter as at the former date. Indeed he felt himself, during the early months of 1886, that he was swallowing more easily; at the same time his strength and weight improved, and a No. 15 bougie could be passed with ease. This favourable condition continued till July, when gradually but steadily the stricture became more severe, and when, in November, 1886, he consulted me, I could with difficulty pass a No. 7 bougie, and the patient was considerably emaciated. The following table of weights in pounds is very interesting, and can be relied upon:—

	1883.	1884.	1885.	1886.	1887.	1888.
January ...	—	151	144	141	132	118
March ...	—	153	142	145	134	112
May ...	156	150	142	145	127	101
July ...	—	145	140	137	128	—
September.	158	143	142	136	125	—
November.	—	143	140	132	121	—

Taking the years from May, 1883, it will be seen that during the first he lost only 6 lb., the second 8 lb., the third gained 3 lb., the fourth lost 18 lb., and in the fifth year 26 lb.; in all the loss was 55 lb. This slow development of the stricture and very gradual loss in weight is in marked contrast to what is seen in other forms of cancer; and even although the case extended over such a long period, the patient did not die from starvation, but as a consequence of secondary formations in the lung. The tumour occupied the lower fourth of the œsophagus, was almost as hard as cartilage, and both in the bronchial glands and in the liver small hard secondary formations were discovered. The nodules at the root of the lung had caused constriction of the bronchi, and very extensive and marked passive pulmonary hyperæmia. We have under observation at present a man (Case 6) whom I believe to be suffering from the disease under consideration.

Soft cancer or acute carcinoma is said to be very rarely seen in any part of the œsophagus, so that the following cases are of special interest. Only one case of acute carcinoma has come under my own notice. But to show you that acute carcinoma is met with in the gullet, I refer you to a case published in the *Glasgow Medical Journal* by Dr. John Fox.[5] I will not occupy your time by referring to the clinical history of the case, but the following is the account of the post-mortem inspection. On examination after death there was found in the middle of the œsophagus a pretty firm mass, about an inch and a half long, and almost completely closing up the passage. The œsophagus, at the part occupied by the tumour, was firmly connected with the structures at the arch of the aorta, but no ulceration of these parts had occurred. The glands at the cardiac end of the lesser curvature of the stomach were enlarged and indurated. The stomach and other organs seemed free of disease. Microscopic examination of the tumour in this case was made by Dr. Joseph Coats, and he writes "that the structure of the tumour presents the characters of medullary cancer, and not of the epithelial form, which is much more usual in the œsophagus. The glands from the neighbourhood of the stomach also present similar microscopic characters." Dr. Joseph Coats informs me that in the Western Infirmary museum he has three specimens of acute carcinoma of the œsophagus, and the patient H. C—— (Case 9), to whom I shall refer hereafter, is also suffering from this disease.

Colloid cancer may attack the œsophagus, but as a rule degenerative changes are seldom observed in malignant growths in this situation. Death of the patient from starvation usually occurs so early after the onset of the disease that little time is permitted for such retrograde metamorphosis to take place. Dr. Bristowe,[6] however, reports one case in which the characteristic appearance of colloid cancer was shown in an instance in which the tumour invaded the lower part of the gullet and the cardiac end of the stomach, as well as formed secondary formations in the lungs and lymphatic glands. The report of the Morbid Growths Committee shows that the tumour presented the "ordinary features of colloid disease, and under the microscope the characteristic alveolar structure was observed."

In considering the diagnosis of carcinomatous disease of the gullet three points require to be considered together—(1) Is there a carcinoma in the gullet? (2) What is its situation? (3) What is its nature? These questions cannot well be discussed separately, for not only do the symptoms depend upon the precise nature of the tumour, but perhaps

even more upon its situation. In respect to situation I will therefore divide the cases which have been brought before you into three classes—(1) those in which the tumour occupied the upper part of the œsophagus; (2) cases where the growth developed at the bifurcation of the trachea; and (3) those instances in which the neoplasm was situated at the lower end of the gullet. Each of these classes may show a different history, and may present special points for consideration.

CASE 3. *Epithelioma (?) of œsophagus at the level of the lower edge of cricoid cartilage; history of steadily increasing dysphagia during two months, terminating in complete obstruction.*[7]—W. F——, aged fifty, a labourer, was admitted into the Glasgow Royal Infirmary on Nov. 3rd, 1890, complaining of complete inability to swallow any food. The only substance which he could take by the mouth was very small quantities of brandy-and-water. He stated that two months previous to admission he experienced a feeling of tightness in the throat on swallowing dry and solid food. This tightness he referred to the region of the larynx, and stated that it had remained always present, although it varied a little in degree from time to time. This constriction, however, increased, so that three weeks ago he was only able to take soft or fluid food. He did not complain of pain. There was no history of syphilis or of injury to the gullet, nor had the patient noticed at any time blood in his sputum. On passing a No. 13 bougie a distinct obstruction was found eight inches and a half from the teeth, and this stricture was so complete that no instrument could be passed through it. On palpating the neck a hard swelling, two inches in length from above downwards, was observed, situated behind the cricoid cartilage and the trachea, but there was no enlargement of lymphatic glands or obstruction to respiration. Physical examination of the chest revealed nothing abnormal.

CASE 4. *Epithelioma of the œsophagus behind the cricoid cartilage; rapid development of dysphagia and dyspnœa, requiring gastrostomy and tracheotomy: good result.*—Mrs. C——, aged forty-three, was admitted into the Infirmary on Dec. 23rd, 1890, complaining of an obstruction to swallowing and slight pain in the throat, which sometimes extended to the ears. On inquiring into the history of the case it appears that she has always enjoyed good health, with the exception of trivial ailments, until the beginning of November, when she complained of pain and dryness at the back of her throat. On examination her medical attendant discovered the pharynx to be deeply congested, and a small ulcer was seen a little to the left of the middle line. Under treatment the condition of the throat improved, the ulcer healed up, and she felt much easier. A few days after this recovery she again consulted her doctor on account of difficulty in swallowing. He passed a probang into the œsophagus and "felt an obstruction on withdrawing it," and he noticed that the bougie was stained with blood. Slight hæmorrhage continued for some hours. Her attendant, Dr. Drysdale, suspected malignant disease; but, owing to the sudden onset of the symptoms, and the almost complete absence of pain, he felt reluctant in expressing an opinion regarding the nature of the disease, and advised the patient to consult me. When I saw her for the first time on Dec. 11th, 1890, she was weak, anæmic, and much emaciated, and stated that for the last three weeks she had been unable to take any solid food, but was still able to take fluid and semi-fluid diet with ease. She told me that since the middle of November the symptoms had steadily become worse, and that during the last six weeks she had lost considerably in weight, and, although she could not give me exact figures, she believed that she had lost about 28lb. On examination, I discovered a hard, firm swelling immediately behind the cricoid cartilage, and extending from the level of the vocal cords downwards for a distance of about an inch and a half. It was found impossible even to pass a small-sized bougie, but on examination with the laryngoscope no encroachment on the lumen of the air passage was observed, either by pressure from behind or by invasion of the wall of the larynx. The voice was perfect, and the movements of the cords complete. On palpation externally, not only was the tumour described above apparent, but there were also several small firm swellings, the largest of which was about the size of an almond, and was situated to the right of the thyroid cartilage, where it was firmly adherent and embedded in the surrounding structures. Considering all the circumstances of the case, I advised the patient to come to Glasgow and have treatment in the Royal Infirmary, where I successfully performed gastrostomy on Jan. 29th.[8] When dismissed, although the lumen of the larynx was encroached upon, there was still sufficient air space to allow of the patient breathing freely. The right vocal cord was fixed in the position of complete adduction; voice good.

In those two cases the stricture was situated high up, and in both the onset of the symptoms and the development of the dysphagia were extremely rapid, so rapid, indeed, in the second case, as to raise a doubt whether the disease was malignant or inflammatory in its nature. This sudden difficulty in swallowing is probably the result of two circumstances. First, the disease involves the narrowest and least distensible part of the œsophagus; and, second, the action of the muscles of deglutition are directly interfered with by the tumour, consequently the food does not pass far enough into the gullet to allow the action of its circular fibres to come into play, hence the greater tendency of food to regurgitate into the mouth or larynx when the tumour is situated high up. In these cases there is still another danger, namely, obstruction to the entrance of air, either by pressure of the growth, leading to diminution in the lumen of the air passages by interfering with the circulation and producing œdema, or by the invasion of the larynx by the new formation.

In Case 4 tracheotomy required to be performed on March 28th—that is to say, eight weeks after the gastrostomy, on account of sudden œdema of the larynx.

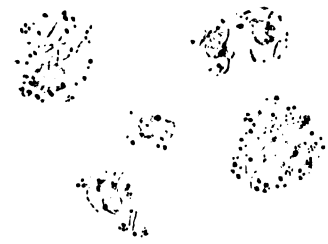
(To be concluded.)

[7] In this case gastrostomy was performed on Nov. 6th, 1890, and the patient lived for exactly one year thereafter. At the post-mortem examination a scirrhous cancer was found at the level of the lower edge of the cricoid cartilage; no secondary formations; old tuberculosis and gangrene of lung.

[8] Patient was dismissed on March 21st, but on account of sudden onset of œdematous laryngitis she was readmitted on the 28th, when tracheotomy was performed, and she returned home much improved on April 25th, and is reported improving in strength on June 22nd, 1891.

THE BEARING OF RECENT BIOLOGICAL RESEARCHES ON THE PRACTICE OF MEDICINE AND SURGERY.

BY G. SIMS WOODHEAD, M.D., F.R.C.P.EDIN.,
DIRECTOR OF THE LABORATORIES OF THE ROYAL COLLEGES OF PHYSICIANS (LOND.) AND SURGEONS (ENG.).



IT has long been known that inert particles of various kinds, when mixed with blood just drawn from the vessels or injected into the circulation of the newt, are rapidly taken up by the colourless corpuscles, where they are enveloped in the motile protoplasm. Particles of vermilion introduced in this way are taken into the amœboid mass of the leucocyte, and in it are passed on from point to point in the channels in which leucocytes are usually found. The number of particles taken up by leucocytes which still retain their power of independent motion is sometimes very great indeed, and it has also been noticed that after a time these particles may be ejected, as though all that could possibly be utilised had been made use of by the cell. In the dust diseases of the lung the proliferating cells derived from the lining epithelium of the air-vesicles have a similar power of ingesting particles of various kinds.[1] These proliferating cells, with their contents, are apparently carried into the lymphatics of the lung tissue; here the pigment may be disgorged, when it is almost immediately taken up by leucocytes or by the stimulated connective tissue cells, or—and this appears to happen very frequently—the wandering cell with its contents is taken bodily into the larger actively stimulated connective tissue or fixed cells, where all that can be digested is converted to the use of the larger cell, and all inorganic matter and effete material is thrown out, to be again taken up, and carried from point to point, until eventually some, at any rate, may be actually excreted from the body or may become enclosed in a fibrous capsule

[1] It has recently been maintained that these cells containing the foreign particles are derived not from the epithelium, but that they are lymphoid cells or leucocytes which have made their way from the blood-vessels and lymphatics into the air-vesicles. It seems to me that we have direct evidence that this is not the case; the partially detached catarrhal cells that contain pigment or other foreign particles being usually well made out in well-prepared sections.

formed by the very fixed cells that took up the particles into their substance, especially in the lymphatic glands. Let us now go a step further. Examine a section of a lung from a case of chronic venous congestion resulting from mitral disease. Here will be found the same catarrhal condition of the epithelium noted above. In the proliferating cells there is also to be seen in some part or other of the section a considerable quantity of golden-brown pigment, usually in small irregular granules. On careful examination some of these catarrhal cells are seen to contain what can scarcely be anything but coloured blood-corpuscles. In most cases the outlines of these corpuscles have become irregular, as they have been altered by digestion by the ingesting cell; but here and there a plumper, more regular corpuscle, which gives us the key to the whole situation, may be seen. From this plumper ingested corpuscle the various transition stages—shrunken corpuscles, mere pigment particles, or even crystals of hæmatoidin—may be seen. These cells in turn are carried to the lymphatics and lymph spaces, where the same cycle is gone through as in the case of the carbon-holding cells above mentioned. If we examine the tissues around a bruised or incised wound after some time we find that two things have happened: the blood-corpuscles retaining the bulk of their pigment have been taken up by leucocytes, where they have been digested and the pigment has been set free, or the fluid in which the coloured corpuscles are suspended has dissolved out the colouring matter, which, however, ultimately finds its way into the leucocytes and thence into the large fixed cells already described.

It is evident from all this that certain cells in the body have the power of taking up not only foreign particles—i.e., particles derived from without,—but also of ingesting effete or dead material of various kinds and of carrying it to positions from which it may be cast out of the body. This function had been conceded to them for some time, when Karl Roser[2] suggested an extension of this function, which afterwards, in the hands of Metchnikoff, who approached the subject from an independent standpoint, was destined to create an interest in leucocytes unequalled in magnitude since the researches published by Hughes Bennett and Virchow. Dr. Karl Roser put forward as part of a theory as to the immunity enjoyed by certain plants and animals against the attacks of the pathogenic fungi that the contractile cells of the animal body have the power of taking into their substance and there digesting even the active living micro-organisms which in non-immune animals are capable of withstanding the attacks of the devouring cells, and of living on their own account in the tissues and fluids, where they give rise to their characteristic products and set up the special manifestations of the diseases with which they are associated. He held, indeed, that phagocytosis was an essential factor in the immunity enjoyed by non-susceptible animals. Metchnikoff,[3] whose thorough biological training had prepared him for the consideration of this important question, approaching it from the point of view of the pure biologist, swept aside much tradition and brought to bear upon it much new light. He already had Haeckel's observations on the blood-corpuscles of the lower invertebrates and their behaviour towards pigment particles on which to base his theory, but he went further back still. He knew well that amongst the lower invertebrates, the amœbæ and flagellated or ciliated unicellular organisms are actually dependent for part of their nourishment upon certain bacteria and fungi which they devour in large numbers, taking them into their substance, extracting from them what they require in the way of nutrition, and then disgorging the degenerated remainder. He pointed out that even one of these small monads is capable of taking into its substance in a very short time (a few minutes) filaments of leptothrix as much as ten times its own length. Here, then, we have living, undifferentiated, or only slightly differentiated cells actually attacking and utilising as a part of its everyday diet micro-organisms similar in many respects to those with which we have to deal in cases of disease.

Continuing his analogy, Metchnikoff pointed out that in animals somewhat higher in the scale of life, and composed of "layers" of specially differentiated cellular tissue, as in sponges, one special layer may still retain this peculiar general power of nutrition, the "mesoderm" cells of which the animal is in great part composed playing the part of the single amœboid protozoa. In the lower invertebrates, indeed, we appear to have the key to the whole position. The whole theory of phagocytosis may be said to depend upon intra-cellular digestion by undifferentiated cells, which cells, in consequence of their imperfect differentiation, retain their "amœboid" motions and powers of irregular contraction. This intra cellular digestion carried on by the lower metazoa is the function upon which they depend in great part for their nutrition. Extra-cellular digestion carried on by means of enzymes secreted by the cells, but thrown out from the cell before they act upon the nutrient material, gradually makes its appearance as we get higher in the scale of animal life, and certain endoderm cells become specially set apart for this process; but even here the mesodermic cells still retain their power of carrying on intra-cellular digestion. Before we leave this part of the question it may be repeated that these imperfectly differentiated cells do not act in mere self-defence in taking up the lower forms of vegetable life, they are actually dependent upon this process of ingestion for their nutrition. It is not an isolated act or a function brought into play for a solitary or rare occasion, but it is a habit upon which the animal depends for its very existence. This fact is the more important when we bear in mind that any "fundamental" function of undifferentiated protoplasm is comparatively easily again brought into play or stimulated into activity when its presence is again required. It is a fact upon which the very foundation of the phagocyte theory depends, though one which has been too much ignored by most of those who have written on the subject in this country. As the extra-cellular digestive function becomes more highly developed less remains for the amœboid cells to do; but, as Metchnikoff points out, in all vertebrates there still remain amœboid mesoderm cells which retain the function or the power of absorbing and removing dead or effete matter, such as weakened or dead cells, foreign particles, and the like. If the development of an ovum, such as that of the cod, be carefully followed, the process of intra-cellular digestion can be easily made out at certain stages in the whole of the cells of which the embryo is composed. Later, however, when the layers are becoming differentiated, and certain sets of cells are becoming specialised, the two kinds of digestion may be seen going on side by side, the more differentiated cells being nourished by extra-cellular digestion, whilst the mesoderm amœboid cells still retain their phagocytic intra-cellular digestive activity. At certain periods of the life history of the incompletely developed animal, when the tail of the tadpole is dropped as it becomes developed into the frog, the degenerating muscles and nerves are seen to be devoured by active amœboid cells, which, commencing at one end of a fibre, gradually bring about its ingestion until the tail actually drops off. In the same way the larvæ of certain invertebrates, such as the echinoderms, lose parts or organs during their metamorphic stages; and whether as cause or effect, particles of the tissue of the disappearing organ or part are invariably found in great numbers of the amœboid phagocytic cells that have accumulated at the point where the absorption is going on; whilst in the metamorphoses of insects, where most profound changes take place in the transition from grub or caterpillar to chrysalis, and from chrysalis to butterfly, phagocytosis is a most important factor of the process. The changes go on so quickly that the rapid removal of effete material is absolutely necessary; and this, apparently, is readily accomplished by the enormous number of leucocytes which collect at those points at which organs or parts are to be got rid of.

Leaving the evidence afforded by the changes that take place during development, Metchnikoff continues his search for analogous conditions in the removal of dead or effete matter in after life, in the higher vertebrates after injury or disease, or even during the process of normal absorption such as that found in Ranvier's experiments on nerve-tissues. This observer found that dead nerve-fibres are removed through the intervention of amœboid cells which appear to take up the myelin of the nerve, and in their substance digest it or carry it away from the point at which the absorption is taking place. That certain cells have this power of absorbing effete matter had long been known, for it had been observed that in the absorption of bone certain large cells, the so-called osteoclasts or giant or myeloid cells, could be seen with granular particles in their interior as they lay in the Howship's foveolæ, which latter appeared to be nothing but excavations made by these large cells. Later still, and since the announcement by Metchnikoff of his phagocyte theory,

[3] Annales de l'Institut Pasteur, vol. i. July, 1887.

Digitized by Google

numerous experiments and observations have been made on the ingestion of resistent particles by phagocytes. Small fragments of elastic tissue and, as we have already seen, of blood-corpuscles have been found in leucocytes, which in turn have been taken into the substance of those larger cells, which are apparently derived from the fixed connective cells. These fixed cells undergoing proliferative changes under stimulation, they lose their specialised form, and although, as a rule, they contain only a single nucleus, they approach comparatively nearly the amœboid leucocyte in the fact that they assume an amœboid activity. These large cells, the *macrophages*, as distinguished from the small multi-nucleated leucocytes or *microphages*, play an important part in determining the ultimate destination of all foreign particles, as already seen in the case of carbon pigment. In this connexion, too, may be noted those cases of the carriage of foreign matter to those parts where the building-up process is going on. In the formation of new bone at the end of the shaft or near the epiphyses there is always found an enormous number of small round amœboid cells, but in addition to these are others which must be looked upon as derived from the fixed connective tissue cells which are now in a state of active proliferation. When young animals during the period of bone formation are fed with madder waste there is formed at the seat of growth a pink layer or zone of bone, and it is pointed out that the colouring matter in this case taken up by the leucocytes is carried in the circulation to the point at which the leucocytes are specially required, the pigment is then given up, or is taken up by the more active connective tissue cells, to be again deposited in the young bone matrix as it is formed by the osteoblasts. That this is not a fanciful explanation of the presence of the pink colour in this position is evident from Arnold's observations[4] on the passage of inhaled pigment of various kinds from the lungs to the spleen, bones, and other organs. The process may be slow in the case of adults, but there is then this additional advantage from the observer's point of view: that once in position it remains much longer than when the development and absorption are going on more rapidly.

These mesoderm cells, then, according to Metchnikoff, have as one of their functions (it may be only a secondary function though he considers that it is the special function as we get to the lower end of the scale of animal life) the devouring of all those solid parts of the organism that have become effete or useless. Where they are unable singly to effect this they are seen to combine in order to attack with greater certainty of success masses which are too large to be enveloped in a single organism. In this manner whole bundles of leptothrix may in a sponge be enveloped in a kind of network which is found to be composed of amœboid cells; these cells combining to bring about what, singly, they could not possibly manage. Particles of organic or other matter when introduced into the abdominal cavities of certain of the echinoderms may, if small, be taken up by single cells; but in the case of large particles a dozen or more of such cells appear to unite to form a plasmodial mass, which in this form is enabled to cope with them. The same thing is observed in the giant cells or osteoclasts of bone, which consist of large masses of active protoplasm, with many nuclei usually accumulated near the centre. It may be objected that these large masses may be the result, not of aggregation, but of imperfect division. This undoubtedly may sometimes be the case, for in the parablast of an ovum, or that layer of cells immediately in contact with the yelk of the egg, we have a mass of protoplasm in which, although there occur proliferation and separation of the nuclei, there is no definite segmentation of the protoplasm itself as it increases in amount and the cell increases in size. In these cases, whether it be in the sponge or in the echinus where there appears to be aggregation, or in the parablast of the ovum of a cod where there is partial segmentation, the vital activity of the component individual cells is not only summated, but greatly increased in the resulting giant cell, in which there remains, after the removal of the special cause of the formation of this large plasmodial cell, an increased power of tissue formation. That is, they have, during this period of increased activity, laid by a store of food and energy, though in the parablast it is utilised by being handed on to the cells in the immediate neighbourhood. In pathological conditions such as tubercle, where giant cells are formed, the extra formative power is utilised in the construction of fibrous tissue or in resisting the invasion of the bacilli. That these cells are actively digesting in the myeloid sarcoma is evidenced by the fact that red blood-corpuscles in various stages of degeneration may be seen, sometimes, however, only in the form of particles of pigment which remain undigested and fixed in the cell longer than the proteids of the corpuscle. Helme has also pointed out that similar giant cells or plasmodia play an important part in devouring the degenerated muscle fibres of the involuting uterus, in which the process of absorption must necessarily go on at a very great rate indeed; whilst coming back to the connective tissue cell, Bevan Lewis maintains that the neuroglia cells, and not the leucocytes, play the part of scavengers in the removal, or rather the taking up and digestion, of dead or weakened nerve elements and tissues. So far we have spoken of the phagocytic action of these cells in relation to dead solid particles, except in case of blood pigment dissolved out from red blood-corpuscles In this case the phagocytes appear to have the power of separating it and in their substance of rendering it insoluble. It is probable, also, that they have the power of taking up and converting within themselves abnormal chemical products which, as pointed out by Wood and Maxwell Ross,[5] are to be regarded in a very real sense as foreign bodies in our organism. If this be true, Metchnikoff's theory must be made to include much that he does not at present allow to come within its range.

In all the examples of the phagocyte theory here put forward the amœboid cells have been looked upon as simply doing the work of scavengers. Their duty is to remove innocuous material, organic or inorganic—or, at any rate, material that has, in the quantities in which it is usually present in the organism, no deleterious effect on the phagocyte cells. In the case of phagocytosis in the single-celled amœba or in the mesoderm of the sponges, on the other hand, the cells actually attack micro-organisms, take them into their substance, and use them as food; so that it would appear as though, in the process of development, this latter power had been dropped, and that, nothing remaining to be done but the "scavenging," except under exceptional circumstances, the more active attacking power had been, in great measure, lost through disuse. Metchnikoff holds, however—and this is the fundamental part of the whole question—that, under certain conditions of stimulation, the scavenging phagocytes regain their original function in so far that, when the call is made on them, especially if this call is led up to gradually, they may not only remove dead tissues and innocuous micro-organisms, but they may actually destroy micro-organisms, which, if introduced without sufficient preparation of the leucocytes for their reception, would not be taken up, but would gain the upper hand, and ultimately lead to damage or destruction of the organism in which the experiment is made. In this case the amœboid cell regains its phagocytic function from the nutritive point of view, whilst its secondary or scavenging power is relegated to a comparatively unimportant position. In order to accentuate this fact, we may here repeat the oft-repeated, but still important, experiments made by Metchnikoff on the daphnia or water-flea with the spores of the monospora biscupidate. In this monospora, which occurs as a budding mycelial thread of elongated cells, long, thin, needle-like spores make their appearance in the long axis of the cells. These needle-like spores are taken into the alimentary canal of the daphnia, through which they are driven by the peristaltic action of the intestinal muscles. Once in the body cavity, or in the tissues surrounding the intestine, it is immediately attacked by the white blood-corpuscles, though in some instances it appears to be taken up by the connective-tissue corpuscles, or, again, it may develop into the rod-shaped vegetative form. If the daphnia is in moderately good health, which under ordinary circumstances happens in about 80 per cent. of the cases experimented on, the monospora is gradually overcome by the active devouring cells. If, on the other hand, the insect is feeble, or if the spores are ingested in such large quantities that they outnumber the leucocytes, or some are left free after all the leucocytes are engaged, these multiply so rapidly that the daphnia quickly succumbs to its attacks. This at first seemed an absolutely convincing proof of the accuracy of the theory that Metchnikoff had advanced; but it was

[4] Untersuchungen über Staubinhalation und Staubmetastasie Leipzig, 1885.

[5] Edinburgh Medical Journal, June, 1891.

Digitized by Google

still objected that here the conditions for the existence of the monospora were not similar to those in which micro-organisms are present in the bloodvessels or in the fluids in which the tissues are bathed. In order to overcome this objection, he took little pith boxes, placed the spores of pathogenic organisms inside them, introduced them into a pocket under the skin or even into the blood-stream, with the result that only the fluid could gain access to them in the first instance at any rate. Nevertheless, the spores vegetated most luxuriantly. Ruffer,[6] repeating these experiments with the bacillus Chauvœi, found that not only were the fluids of the body innocuous; but that they actually formed an excellent culture medium, in which the organism could grow, and attenuated micro-organisms regain much of their pristine virulence. He found, for example, that when the attenuated bacillus Chauvœi supplied for purposes of vaccination was placed in small bags made of filter paper sealed with paraffin and then introduced under the skin of a susceptible animal, and even of a non-susceptible animal, it grew luxuriantly. If now the bag was broken *in situ*, so that the organisms could find their way into the tissues, or if the bag was cut out immediately after the animal had been killed with chloroform and the contents inoculated into a second animal, it succumbed sometimes after a shorter period than when ordinary virulent material was inoculated. In this case therefore the fluids cannot have any deleterious effect on the micro-organisms, so that any destruction of these that takes place after inoculation in the ordinary fashion must be accounted for, according to Metchnikoff and his pupils, by the phagocytic action of the amœboid cells. The action of pus-producing micro-organisms, the spirillum of relapsing fever, and the bacillus anthracis have all been fully studied in their relation to phagocytes; but one organism has been taken as the one by which the phagocyte theory is to be tested.

It is objected by the opponents of the theory that the leucocytes (microphages) are always a little too late to catch the erysipelas streptococcus, the organism being found in a zone always a little beyond that in which we have any evidence of inflammation. Wood and Maxwell Ross[7] showed that, although this was undoubtedly the case, the following inflammation appeared to exert a curative influence, in so far as it appeared to cut short the infective process. Metchnikoff[8] and Fehleisen, describing the appearances presented on microscopic examination, give first of all an outermost zone, where the erysipelas is spreading, but which to the naked eye appears almost normal, in which the micrococci, multiplying rapidly, completely fill the lymphatics. There is little or no evidence of inflammatory reaction. Passing inwards, however, we come to a zone in which inflammatory reaction has set in. The vessels are dilated, the fibrils of the connective tissue are swollen, and surrounding the small vessels and lying in the lymph spaces are numerous amœboid cells, leucocytes, or microphages, which, like their amœboid types, are acting the part of devouring cells, as many of them contain micrococci, sometimes in considerable numbers. The micrococci are usually so readily stained that they may easily be recognised in specially prepared specimens. Now comes the interesting point. In the next zone these smaller cells with their contents are in turn devoured by the larger amœboid cells—macrophages, probably derived from the fixed connective cells, and each containing a single nucleus only. After this the organisms found in the tissues over which the disease has passed contain only dead and degenerated micrococci; so that, as Wood and Maxwell Ross say, "It would thus seem that the wave of congestion, accompanied as it is by a diapedesis of the white blood-corpuscles, has, in fact, cut short the course of the disease." Arguing from this, they decided that if they could set up a certain amount of inflammation they could cut short the duration of the attack; in fact, that they might be able to localise it more or less completely according to the stage at which the disease came under treatment. They therefore decided to use iodine as a local irritant, applying it "in the form of a ring *slightly beyond that portion which is already affected.*" They say, "It is naturally very important that inflammation should extend beyond the limits of the disease in order that it may act as a barrier to its further progress. It is, we think, very probably to the fact that the microbes have already penetrated in the tissues beyond the point where we have the visible signs of their action that we must ascribe the statement so frequently made, that although the treatment with iodine and with other irritants exerts a checking influence as a whole, yet at some point or other the affection still continues to spread. We may in these cases suppose that at some places our zone of irritation was not sufficiently in advance of the presence of the erysipelas cocci. The application of the irritant over the whole surface of the affected skin seems also, on the whole, undesirable, inasmuch as, in consequence of this, the dilatation of the vessels at the margins, which we have considered as the most important factor in the cure, must be interfered with by these being drained into the collateral vessels of the skin, and thus tending to diminish the intensity of the process in this region." Basing their treatment on what had been observed, and bearing in mind the nature of the disease and of the spontaneous cure, they painted with iodine in the manner above described patients suffering from erysipelas, and in all cases where there was any chance of treating the disease the results obtained were most satisfactory, as the barrier of inflammation so set up appeared to serve its purpose most effectually. These observers, however, do not allow that the only effect of the inflammatory process is to bring up phagocytes to cope with the micrococci; they maintain, indeed, that there are two other very important factors to be taken into consideration. They hold that the dilatation of the vessels with the increased flow of blood may allow of the toxines produced by the microbe (which are said to have a paralysing effect on the phagocytes, which are thus unable at first to ingest the active living microbes), whilst, in the second place, they think that the relatively increased supply of oxygen brought up by the increased quantity of blood may be sent on to "the lymphatics, where the oxygen tension must naturally be very low. That this will favour the tissues rather than the microbes in their struggle is evident, when we consider that the streptococci of erysipelas in the animal body flourish best under anaerobic conditions, as is indicated by their strict limitation to the lymphatics." But they say that "the checking of the disease ..... by applying an irritant, such as iodine, in advance of it, indicates that the irritation to the cells and the new set of conditions thereby induced can alone cut short the affection." Since the publication of the paper here referred to, Dr. Alex. Miles, who assisted in carrying on the first series of experiments, has treated a large number of cases of erysipelas with marvellously successful results—results which, I am informed, will shortly be published.

It has been stated above that in the outer zone of the erysipelatous area the cells appear to be paralysed so that they cannot take up the micro-organisms. De Bary observed that in myxomycetes there were certain substances which, when brought near the plasmodium, exerted a vigorous repellent effect, so that it was energetically driven off. If, however, care was taken to bring these same substances near the plasmodium in sufficiently small quantities and sufficiently diluted, the organism would gradually become habituated to the presence of even the concentrated dose. Applying this fact, Metchnikoff pointed out that acquired immunity might be due to a similar kind of acclimatisation of the cells to the presence of what, under ordinary conditions, would not allow the cells to come into sufficiently close contact with the microbes to allow of their ingesting them. This power can undoubtedly be greatly modified, especially if the conditions be modified very gradually and slowly, and cells which at first would be quite incapable of reacting in the presence of a specific poison may ultimately be able to withstand and perform their special phagocytic functions in the presence of considerable doses of this same poison. For example, Beumer and Peiper[9] have demonstrated that if a certain dose of the poison produced by the typhoid bacillus will poison an animal, paralysing the amœboid cells, the same dose may be given to an animal that has been carefully prepared by the administration of repeated—at first small, but gradually increasing—doses of the same poison. The phagocytes are educated, or acclimatised as it were, to their new set of conditions, their original power of devouring even pathogenic organisms is regained, and the disease is kept under, as in the case of the healthy daphnia in which the dose of spores is not too great.

(To be continued.)

ON SOME PAINFUL AFFECTIONS FOLLOWING INFLUENZA.

BY A. ERNEST SANSOM, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL, ETC.

I PROPOSE in this short communication to pursue the inductive method of reasoning in regard to some cases which at one time caused me considerable perplexity. I will first mention a case which initiated my difficulties. A gentleman aged fifty-three, who for many months previously had been in fair average health, was taken during the night with severe pain in the right hypochondrium. The signs simulated those of hepatic colic. He took a mild aperient, and the attack passed away after one to two hours and he slept. The following day the bowels were properly opened, there was no evidence of absence of bile from the motions, the urine was in all respects normal and contained no bile nor excess of colouring matter. The attacks of severe pain, however, recurred at intervals—mostly in the night, but sometimes during the day—for about ten days, treatment by opium and belladonna only relieving them. It seemed that the gall-bladder could be mapped out by the area of tenderness, but never was there the slightest jaundice. On one night there was sharp diarrhœa. I could only say that the attacks were those of hepatalgia of paroxysmal recurrence. In hunting about for a cause the only antecedent which seemed at all probable in this direction was an attack of influenza contracted in Paris at the very earliest time of the epidemic, and followed by protracted enfeeblement. I computed that nearly twenty months must have elapsed between the original attack and these consequences, if they were consequences. There was no evidence of reinfection, but of course this was possible.

The key seemed to be furnished by a number of experiences which came to me just about the same period as this first instance. In all there was fair evidence of an attack of influenza followed at intervals, extraordinarily variable, by signs of extreme pain and distress. In twenty-four such cases the sites of pain could be thus tabulated:—1. Epigastrium, nine cases; abdomen generally two cases; localised in hepatic area, one case. 2. Head, various sites, seven cases; supra-orbital region, one case; right inferior maxilla, one case. 3. Heart region, seven cases. 4. Extremities: hips and legs, two cases; calves, two cases; arms, two cases; right sciatic region, one case; fingers, one case; lumbar region, one case.

In Group 1 in some cases the pain at the epigastrium was nearly constant. For instance, a man aged sixty-six, who had been previously quite healthy, caught influenza at Christmas 1890, and had never felt well since. Six months afterwards he had constant pain at the epigastrium, with craving for food. Food slightly relieved the pain, but soon after nausea occurred, with pyrosis. In most cases the pain was paroxysmal, and frequently nocturnal, sometimes attended with vomiting or pyrosis. Peculiar symptoms occurred in some of these cases, as "a feeling as of a cold wind over the chest, and inability to take a deep breath." In some the signs of colic, as in the first case mentioned, were closely simulated; frequently there was retching, but the tendency was rather to diarrhœa than to constipation. In one case, a man of sixty-three suffering from intense epigastric pain, with sense of heavy weight preventing sleep, and some vomiting, I found a small patch of herpes zoster below the angle of the right scapula.

In Group 2 were various neuralgiæ. In one man aged thirty-eight there was intense supra-orbital neuralgia varying from side to side; previously there had been rigor and abdominal pain like colic, and then sweating and palpitation. He had suffered from influenza twelve months previously, but no ailment since. In another case, a lady aged twenty-five, urticaria followed influenza, and twelve months afterwards attacks of vertigo, with palpitation of the heart and pain referred to the occipital regions. A lady of thirty-seven, who had suffered from an attack of influenza in May, 1891, averred that two months afterwards she commenced to have headache, from which she had never been free in her waking hours for three months subsequently; she also suffered from pain on movement of the right lower jaw. She had tremors and tinnitus aurium, but no vertigo. In others headache occurred coincidentally with gastric crises.

In Group 3 some of the patients referred the pain which they suffered very closely to the region of the heart. In a few cases the pain was persistent, but in most paroxysmal. A lady aged forty-two, who had suffered from influenza nine months previously, described the pain as constant and dull, limited to the heart region. A gentleman aged thirty-six, whose attack dated sixteen months previously, was wearied with such dull aching; it was rather more diffused than in the former case. In another gentleman, aged forty-two, the constant pain in the cardiac region was accompanied by a tingling down the left arm The most important and characteristic cases in this group, however, simulated angina pectoris. A gentleman aged thirty-one, typically athletic, who had never suffered from illness before his attack of influenza, which was very severe, was taken five months afterwards with sudden and violent pain at the heart, eventuating in syncope. He was standing with his back to the fireplace, talking with friends, when the attack seized him with violence, and he fell unconscious upon the hearth-rug. There was no epileptoid sign. Another attack occurred a week after. There could be no doubt from collateral evidence that the patient became faint to unconsciousness. In the intervals no notable deviation from health could be detected; the left ventricle was slightly hypertrophied, but not more so than could be expected in an athletic subject The patient described the pain as of the character of a "grip" or "screw" at the heart; he experienced no coldness, and repudiated any sense of impending death. There were occasionally also some attacks of dyspnœa, occurring independently of exertion. Nearly at the same time at which this patient came under my observation a gentleman came under my care with like symptoms, in whom there was no evidence of an attack of influenza. He presented the appearance of typical good health, but suffered attacks of terrible pain at the heart, ending in complete unconsciousness. On some occasions the attacks were followed by wild excitement, and the patient had to be restrained from self-violence. I have reason to believe that in both these cases there was complete recovery. In a lady, aged forty-one, attacks of intense pain were initiated by exertion. The pain was localised in the second left intercostal space—presumably over the superior cardiac plexus—and here was a tender spot. The pulsations of the heart were painfully felt when in the recumbent position. In some other cases there was a feeling of impending death, as in true angina pectoris, though the pain was much less severe. This occurred in a gentleman aged thirty-three, sixteen months after an attack of influenza. Pain referred to the heart, however, had occurred at intervals ever since his attack. In the case of another gentleman aged thirty-seven, the sensation was described as of an arrest of the heart, as if the pendulum of a clock had been stopped at one swing. With this the patient said, "I feel as if I were going to die." In some cases there was a manifest slowing of the pulse; in others an irregularity. Sometimes a slow alternated with a quick pulse. Fifteen months after an attack of influenza I counted the pulse of a lady aged twenty-two as fifty-six. In most cases the rate was rapid, and I do not remember one case in which the arterial tension was unduly prolonged. This absence of prolonged arterial tension, in my opinion, took the cases out of the category of true angina pectoris. I have not heard that any case was fatal.

It is no part of my purpose to pursue the question of the cardiac phenomena of influenza. These furnish most interesting lessons, but I am concerned now only with the manifestations of *pain*. I turn now to Group 4, in which there were painful affections of the extremities. A lady aged twenty-five, who had an attack attended with high fever four months previously, complained of intense aching in both arms. This occurred chiefly at night, and she actually wept on account of the pain. Previously to the manifestation in the arms she had suffered pain in the calves of the legs resembling that of neuritis. In another case of a gentleman aged forty-one, the pain was referred to the lumbar regions more on the left side, to the right shoulder and the left wrist, to the course of the right sciatic nerve, and to the muscles of the thigh. There were fearful exacerbations, chiefly nocturnal, so that the patient, previously a healthy man, actually shrieked on account of the pain. In the case of a female aged thirty-three pain was localised in the muscles of the calves of the leg and of the thigh. The pain was strongly aggravated after food, especially meat. In another female, aged twenty-three, pain was extremely violent in the thighs and legs, and there

Digitized by Google

were attacks of faintness. Subsequently the suffering was localised in the course of the right sciatic nerve. It was subject to remissions with severe nocturnal exacerbations; there were also shooting pains at the epigastrium. The case was of alarming intensity, but recovered. In a lady aged forty-eight pain was referred to the right hip and to the right arm; it extended from the right shoulders to the fingers, and all movement caused pain.

There could be little doubt that in these cases there was a form of neuritis. I met with other analogous instances in which there had been no history of influenza: one case in a child in whom there was severe pain in the calves, dropped feet, absolute loss of motor power, and, in fact, all the signs of neuritis of the alcoholic form. Any causation by alcohol was in this case quite out of the question; no doubt it was due to some infectious cause, and resembled the cases of peripheral neuritis, due to no traceable contagion, recorded by Dejérine and others.

In this summary of my personal experiences I have dealt with no cases of the earliest manifestations of influenza; all were in patients whose attack had passed away and who were not confined to their homes. The periods between the attack of influenza and the manifestations of symptoms of pain varied from a few weeks to twenty months.

The evidence appears to me to confirm the view of Dr. Althaus that the *materies morbi* of influenza resembles the syphilitic virus in its tendency to attack many parts of the nervous system after the attack is over, but surpasses the syphilitic toxine in virulence and in rapidity of action. Dr. Althaus[1] has adopted the deductive method in his reasoning. Starting from certain probabilities, he has worked out the problems of the effects of the *materies morbi* if it should specially attack certain areas of the central nervous system. He concludes that the different forms of influenza are due to irritant poisoning of the bulb and the nerve nuclei contained in it. Adopting a converse method, that of logical induction, and taking my arguments alone from personal experience, I have arrived at a similar conclusion to Dr. Althaus in so far as the proposition is concerned—that the virus of influenza especially affects the nervous system. Leaving the question of the acute and early manifestations, however, which I agree with Dr. Althaus in considering to be due to involvements of certain areas in the medulla oblongata, it appears to me most probable that the consequent phenomena are better to be explained by inflammatory changes in certain peripheral parts of the nervous system. In regard to the *visceral neuralgiæ*, the hepatalgia, the gastralgia, and cardialgia, there are signs of localisation and, in some instances, of local tenderness that point to a local cause. In some such it seems probable that the sympathetic fibres and ganglia are alone affected. In other cases, as in those in which there seems to be temporary arrest of the heart's action, retching, vomiting, and various disturbances of digestion, it is most probable that the vagus is involved in greater or less degree; but here also the effects might be due to peripheral irritation. In the sensori-motor manifestations it can scarcely be possible to avoid the conclusion that there is in existence a form of neuritis analogous to that which is caused by many other toxines. The conclusion, therefore, which I have come to is that the various affections I have briefly described are the remote consequences of the influenza infection, and that their proximate cause is a peripheral neuritis affecting the sympathetic ganglia and nerves, the vagus, and the sensori-motor nerve trunks.

Harley-street, W.

[1] THE LANCET, Nov. 14th and 21st, 1891.

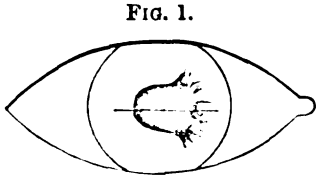
ON THE TREATMENT OF SPREADING ULCER OF THE CORNEA WITH HYPOPION.

By RICHARD WILLIAMS, M.R.C.S.,

SURGEON TO THE LIVERPOOL EYE AND EAR INFIRMARY, AND OPHTHALMIC SURGEON TO THE ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

FEW affections of the eye are more rapid in their progress or more destructive in their consequences than those cases of ulcer of the cornea with a collection of pus in the anterior chamber, and yet I believe there are not many affections more amenable to prompt and appropriate treatment. I propose in this paper to introduce a method of dealing with these cases which, as far as my knowledge extends, has not hitherto been in general use, and which consists, first, in the local application of quinine; and secondly, in a modification of the usual incision for the evacuation of the pus contained in the anterior chamber. I am able to speak of this method of treatment after an experience of several years, during which I think I have had ample reason to be satisfied with its results. As is well known, these cases are met with among the debilitated of all ages, most frequently as the result of traumatism. Among the colliers of the Wigan district they occur with unusual frequency, and I venture to assert, therefore, that my experience of them is above the average. In their treatment I have employed a solution of quinine during a period of upwards of ten years. The following mixture is used in nearly all cases that come under my care: R. quiniæ sulph. neutr., gr. iv.; liq. atropiæ sulph., ℥ i. M.; ft. guttæ. In simple ulcers without hypopion I am in the habit of prescribing eserine much oftener than atropine, but I invariably prescribe the latter drug where hypopion is present, because iritis is a common feature in this condition. I doubt if either eserine or atropine has any appreciable influence upon the suppurative process. On the other hand, there is hardly anything in medicine about which I entertain less doubt than that quinine locally applied has an immediate and powerful influence in arresting this process and in causing the absorption of the pus already collected in the anterior chamber. I believe I have had repeated evidence of this both in my private practice and public clinique.

It is not my intention to burden this paper with a number of cases which seem to me all to tell the same tale, but I cannot refrain from quoting the following case, which I think not only shows the value of quinine, but also tends to prove that atropine and eserine by themselves have no great, if any, influence upon the process of pus formation:—



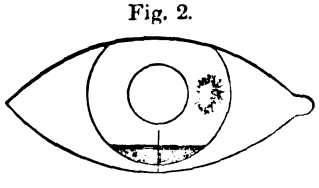
D. J——, aged eighteen, was admitted into the Eye and Ear Infirmary on June 24th, 1882, for capsular cataract due to an injury five years previously. I am indebted to Mr. Shears, who was then house surgeon, for the following notes of the case:—Soon after admission the opaque capsule was removed *en masse* by means of the cannula forceps, and two days later the patient, whose vision before the operation only amounted to perception of light, could count fingers with ease. The following day a hypopion appeared, and atropine and belladonna fomentations were ordered every three hours. On the 28th, the hypopion still remaining, quinine was added to the drop.—29th: "Hypopion much smaller."—July 1st: "Hypopion gone." The quinine and atropine drops were continued until the 8th, and eserine substituted.—12th: The hypopion reappeared, and the quinine and atropine drop was again used.—14th: "Hypopion gone, muddy condition of anterior chamber clearing up."—17th: Atropine alone was ordered.—19th: Hypopion reappeared with pain and injection; atropine and quinine drop again resorted to.—22nd: "Hypopion gone."— 26th: Patient discharged. $V = \frac{20}{30}$ c. + 6 D. J. 1, c. + 12 D. It will be noticed that in this case the hypopion made its first appearance while the patient was under atropine, and that it quickly disappeared when quinine was added to the drop. Its reappearance took place each time when the quinine was omitted, although the atropine or eserine was still continued. In other respects the treatment was not varied, the patient taking quinine internally from the first appearance of the hypopion.

I may also mention a recent case recommended to me by Dr. Bouverie MacDonald of Liscard. Mr. McW——, aged nineteen, had only complained of his eye about thirty-six hours before he was sent to me. I found an abscess of the cornea and a large hypopion. The cornea generally was hazy and the aqueous turbid. The conjunctiva was slightly chemosed and discharging muco-purulent matter. In fact, the disease had been sudden in its onset and extremely rapid in its progress, and I have no doubt that a delay of twenty-four hours would have seriously compromised the safety of the eye. I ordered quinine and atropine drops, to be used every two hours, and quinine internally three times a day. No other treatment whatever except a pad and bandage was employed. Two days later there was a marked improvement, and in four or five days the hypopion had completely disappeared. It may be argued that these cases often recover under atropine or eserine, hot fomentations, and antiseptic lotions, and that they are no proof of the value of quinine locally applied. It is obvious that positive proof is practi-

Digitized by Google

cally out of the question in cases of this description, and it is only after comparison of a long series of cases treated by both methods that anything like an authoritative opinion can be ventured. A vivid recollection of the frequency with which these cases went from bad to worse in my earlier years leaves no doubt in my mind of the immense superiority of the quinine treatment. I am far from saying that all cases of hypopion can be made to disperse by means of quinine; but I am constantly seeing cases in which, in my judgment, the process is quickly arrested, and which would otherwise inevitably require operative measures. Old cases where the pus has become mixed with fibrinous material will no doubt require evacuation, but I believe that even then the use of the quinine drop exerts a powerful influence in preventing the reaccumulation of the pus. Before leaving this part of the subject, I may say that patients make no unusual complaint of smarting in using the drops. An aqueous solution of the soluble quinine is innocuous, and can be used as frequently as necessary without the least detriment to the eye. Coming, then, to those cases where the evacuation of the pus by operation is imperatively demanded, the question arises, What is the best method of performing paracentesis? There are two methods in ordinary use: First, by making a horizontal incision, parallel with the margin of the cornea, just underneath the purulent collection; and secondly, Saemisch's incision, which consists in passing the knife into the anterior chamber at the spot where the ulcer may happen to be and dividing it through and through, as shown in Fig. 1, the

FIG. 1.



Saemisch's incision. After De Wecker.

blade entering the anterior chamber and emerging from it in healthy tissue.

To the first of these incisions I think there are serious objections. 1. The anterior chamber does not empty itself well, especially when the knife is slowly withdrawn, as is generally advised. 2. There is considerable danger of prolapse of the iris. 3. There is the maximum danger of interference with the nutrition of the cornea, because more of the nutritive channels, which are radially arranged, are involved in the incision. In fact, the only advantage this incision possesses, as far as I can see, is that it leaves no visible scar. Personally, I have entirely abandoned it for several years. Secondly, Saemisch's incision. I believe the good effect which undoubtedly follows this incision is due, not to the fact that the ulcer is cut through, but because the anterior chamber is more thoroughly emptied of the pus. On the contrary, any incision of an already attenuated and weakened part of the cornea must, it seems to me, be in itself injurious. I have not seen any reason advanced for dividing the ulcer itself as practised by Saemisch, and, unless it can be shown that this method possesses some curative influence other than is brought about by the thorough evacuation of the anterior chamber, I believe an incision in healthy tissue is decidedly to be preferred. Moreover, it is evident that if the ulcer should happen to be situated in the upper two-thirds of the cornea, the evacuation of the contents of the anterior

Fig. 2.

chamber must be a matter of some difficulty; and this is probably the reason why authors generally agree that the incision should be reopened daily for some time. It requires no great knowledge of the subject to see that this reopening of the chamber is a great drawback to the progress of the case. It prevents healing and greatly facilitates the formation of anterior synechiæ, not to speak of the pain and the annoyance it gives a patient already reduced and little able to bear them.

Basing my practice on these considerations, I now always make the incision as shown in Fig. 2. I introduce an ordinary Graefe's knife into the anterior chamber underneath the purulent collection, and carry it directly upwards in the direction of the pupil, care being taken not to enter the pupillary area. I withdraw the knife rather quickly with a forward motion, and the result is that the aqueous escapes with something of a rush, carrying with it the purulent mass which generally sticks between the edges of the incision, where it can be easily picked out with a pair of forceps. Any remaining fluid pus immediately follows, and the anterior chamber is left perfectly empty. I think this incision has distinct advantages over the others to which I have referred. 1. It is made at the seat of the purulent collection, and being *in the line of pressure* from behind, the evacuation is as complete as it can be. 2. Being made in the direction of the nutritive channels, it offers the minimum of interference with the nutrition of the part. 3. Prolapse of the iris is impossible, because the effect of pressure of the muscles upon the globe is to bring the edges of the incision together, and so effectually to prevent protrusion of the iris. 4. Being made entirely in healthy structure, it heals by first intention, and I *never have occasion to reopen it*. If, after practising this incision, the case goes from bad to worse, it is not because the anterior chamber requires to be reopened, but because of the continued spreading of the ulcer. I have no doubt, however, as already mentioned, that the use of the quinine drop after the operation has much to do with preventing the reformation of the hypopion. In the event of the ulcerative process continuing and threatening, as it sometimes does, the entire surface of the cornea, I consider the actual cautery the most effectual means at our command for arresting the spreading process. In conclusion, I think the only objection likely to be advanced against this incision is that it leaves a scar; but I consider this a purely theoretical objection. The incision need never encroach upon the pupil, hence no interference with vision need be apprehended, and the scar, being linear, is practically invisible against the background of the iris.

Liverpool.

SOME CASES OF RENAL COLIC.

BY NESTOR TIRARD, M.D., F.R.C.P.,
SENIOR ASSISTANT PHYSICIAN, KING'S COLLEGE HOSPITAL; PHYSICIAN TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

IN dealing with any case of severe abdominal pain, which recurs from time to time in a paroxysmal way, it is usual to make inquiries as to the precise starting point of the pain, and the directions in which it radiates, and to ascertain the occurrence of any accompanying symptoms which may throw light upon the diagnosis. The information thus gained will frequently form the foundation for further investigations, and thus the clinical features of the case may often be elucidated with ease. Thus a woman aged fifty, who was recently under my care at King's College Hospital, gave the following account of herself: Until three years ago she had had no serious illness, but at this time on several occasions she passed blood with her urine, and this hæmaturia was mostly accompanied, preceded, or followed by somewhat severe lumbar pain in the right side. After these attacks there was frequently more or less acute pain on micturition, which, however, gradually subsided. The association of hæmaturia clearly pointed to the renal origin of the colic, and, although the pain in these earlier attacks does not appear to have been as severe as usual in cases of renal colic due to calculus, there was no difficulty in arriving at a diagnosis, since the immediate cause of her appearance at the hospital was an attack of very severe pain, during which she was repeatedly sick, and on examination the urine was found to be highly charged with blood. Mostly the passage of the first renal calculus along the ureter is attended by more pain than in later attacks, since the ureter becomes more distended each time a calculus passes along it, and thus offers but little opposition to the passage of a small calculus. In this

Digitized by Google

case, however, there could be no doubt that a calculus of much larger size than usual was making its way down the ureter, or perhaps had already reached the bladder. All cases of acute abdominal pain do not disclose their etiology as readily. The common causes of true colic are hepatic, nephritic, and the form due to lead poisoning. Renal colic usually commences somewhat acutely in the region of the kidney and shoots downwards towards the groin, sometimes being associated with aching and tenderness of the testicle, or even with pain on the inner side of the thigh. Sometimes, however, it passes upwards from the original site, so that tenderness or actual pain is referred to the angle of the scapula or even to the shoulder-tip, and then it is most important to consider the associated symptoms to distinguish the case from one of hepatic colic, in which the pain, starting in the right hypochondrium, radiates backwards and upwards in the direction of the shoulder. A short time ago I saw such a case in consultation, where, in the absence of hæmaturia, the vagueness of the localisation of the pain and the indefinite way in which it radiated, left considerable doubt as to its nature, until the appearance of bile in the urine rendered it certain that we were dealing with hepatic colic. In cases of lead colic the pain appears to start at almost any point within the abdomen; but it is referred mainly to the region of the umbilicus, and is generally relieved by pressure. Although by thus endeavouring to trace the course of the pain a great deal may often be learnt, occasionally the indications are misleading. Thus a case I saw in consultation a few years ago baffled all concerned. It was in a schoolboy aged twelve, in whom there was a history of hæmaturia, with severe pain, after another boy had jumped suddenly and roughly on his back. There was only this one attack of hæmaturia, but from this time there were frequent complaints of severe pain, which seemed to return with any sudden jolting movements, a railway journey or a ride in a hansom cab often proving sufficient exciting cause. It was also noted that the pain was worse with constipation or with acute diarrhœa. Digestion was imperfect and the urine contained numerous crystals of oxalate of lime. Although no certainty was felt about the presence of a renal calculus, it was generally thought that the symptoms might be due to this, and that an operation was advisable as affording the best prospect of relief. At the operation no stone could be found, although the pelvis and the substance of the kidney were carefully explored by a needle. A firm cicatrix was, however, discovered uniting the capsule of the kidney and the descending colon, and this was so tough and so extensive that it was deemed expedient not to divide it. This, then, furnished the explanation of the symptoms and the occurrence of pain after intestinal irregularity. The lad recovered, and is now able to keep fairly free from pain so long as he attends closely to the action of the bowels. As a parallel case I may mention another which has interested me greatly during the last two years. The patient, a young lady, first complained of increased frequency of micturition with pain, and the urine was found to be charged with pus. Considerable improvement followed the administration of alkalies, and later I continued to hear good accounts of her progress when she was treated by a surgeon with vesical injections of nitrate of silver. Eighteen months after the onset of cystitis she again came under my care for sudden severe pain in the lumbar region, far more intense than any pain she had previously suffered, and accompanied by sickness and by complete prostration. She has now had several of these attacks of renal colic, and the deeply interesting fact has been ascertained that for a short time immediately before one of these severe attacks the urine has usually been remarkably free from pus, but that shortly afterwards it is once more turbid and opaque. Clearly the explanation is that, although the case started with simple cystitis, the inflammation has extended to the pelvis of the kidneys, and that one ureter is occasionally blocked by a thick tenacious clot.

The pain in ordinary cases of renal colic has been variously attributed to direct irritation by the calculus, which is occasionally of a mulberry form, or to the over-distension of the ureter above the calculus. Neither of these explanations appears to me quite satisfactory. I believe that the cause may be gathered by reference to the other common forms of colic. The bile is secreted at such low pressure that hepatic colic can scarcely be due to over-distension, while gall-stones are usually so smooth that, in spite of their facets and angularity when multiple, it would seem unlikely that direct irritation can result. In the case of lead colic there is no stone to cause either severe local irritation or over-distension, but the cause is usually sought in temporary paralysis of a portion of the intestine. In the three, however, there is one condition common to all—viz., severe spasm of involuntary muscle; and in spite of the occasional abrasions which have been found in the lining membrane of the ureters, I believe that this muscular spasm should be regarded as the immediate cause of the pain. This view is further supported by the analogy of the pain of ordinary flatulent colic, and by the pains and after pains of labour, when the uterine contractions become exaggerated. Renal colic is undoubtedly the result of any attempt of a calculus to pass down a ureter of insufficient calibre, and it does not seem that the pain has any relation to the shape of the calculus or to the amount of local abrasion, but that it depends mainly on the amount of involuntary spasm which is excited by the presence and the size of the calculus. This contention is further supported by the result of treatment. In these cases it is customary to employ opium or morphine, and further relief is frequently afforded by a hot bath. The first doubtless relieves pain by its general anodyne action upon the nervous system and by blunting the sensibility it renders the condition less unendurable. The action of opium, however, extends also to the relaxation of muscular spasm, and in this action it is aided greatly by the influence of heat. Further, the pain travels downwards along the length of the ureter, and it frequently ceases almost entirely after the stone has passed into the bladder, the acute, agonising pain being followed merely by a dull aching, which gradually passes off. This last pain is, I believe, the result of irritation, while the acute pain is produced by muscular spasm.

Weymouth-street, W.

PLEURAL EFFUSION AND EMPYEMA.[1]

BY JAS. ALEX. LINDSAY, M.A., M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE BELFAST ROYAL HOSPITAL; CONSULTING PHYSICIAN, ULSTER HOSPITAL FOR WOMEN AND CHILDREN.

IT is with some hesitation that I undertake to direct the attention of the Ulster Medical Society to so familiar and well worn a subject as pleural effusion and empyema. I am encouraged to do so because the diseases in question, however familiar, possess a very exceptional clinical interest, and because there are many points in connexion, especially with their etiology and treatment, around which much controversy has raged, and still rages. I have a further reason for inviting attention to this topic—viz., that it is one which concerns and interests not only physicians but surgeons, and I rejoice that in the goodly array of speakers who are to follow me are to be found the names of several of my surgical colleagues. Permit me to say that I have given the subject special attention for several years, and that my opportunities for observation have been considerable. My remarks will be based mainly on a series of thirty-five cases, about which I possess full information. I have also partial records of a number of additional cases, bringing up the total to about fifty, and these partial records will be available for at least a portion of our inquiries. I can hardly hope that my facts will be new, but they will be at least facts, and not mere theories or book-work.

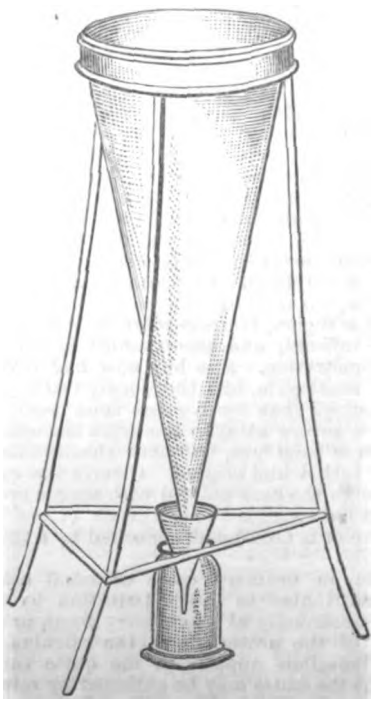
It will be obvious that to handle exhaustively so vast a subject as pleural effusion and empyema within the compass of a single paper would be altogether impossible. I shall therefore make no pretence of covering the entire ground, but shall select a number of points which seem to offer the best prospect of affording us something of interest and value. Without further preliminaries, therefore, I proceed to consider the first question which I have put down for discussion—viz, is simple pleural effusion commonly due to (*a*) exposure, (*b*) rheumatism, or (*c*) tubercle? In this country exposure has been usually regarded as a common and adequate cause of pleurisy. On the Continent, however, the tendency has been rather to regard the affection as due to some specific cause, either rheu-

[1] A paper read before the Ulster Medical Society.

Digitized by Google

matism, tubercle, pyæmia, or cancer. I have inquired into this point as carefully as possible, and from an analysis of thirty-five cases have obtained the following results. In sixteen cases, or nearly half the total number, there was a clear history of either a wetting or exposure to cold when the patient was heated and perspiring. Rheumatism was present in three cases, one of them being a case of rheumatic fever. There was a family history of tubercle in two cases, and in three cases the patient had suffered from hæmorrhage, probably of pulmonary origin. In ten cases, or nearly a third, no cause whatever could be assigned for the attack. None of my cases were either cancerous or pyæmic. That this question of etiology is a complicated one will appear from the fact that in one of my cases there was a clear family history of tubercle, the patient was rheumatic, and the onset of the pleuritic attack was attributed to exposure. On looking over the figures which I have just given, one is disposed to ask what value is to be assigned to the history of exposure and cold, to which patients in this country are so ready to attribute the most diverse ailments. With every desire to scrutinise critically such histories, I feel that the facts which point to exposure as a cause of pleurisy are too palpable to be overlooked and too numerous to be the result of mere coincidence. Not only were half of my cases attributed to this cause, but in many of them the history was precise and definite. In five cases the attack followed a severe wetting. In one case a lad, apparently quite healthy, slept upon a stone floor, and was immediately seized by acute pleurisy. In many of the remaining cases the patient was exposed to cold air when hot and perspiring. The argument that pleurisy cannot be due to simple exposure, inasmuch as other serous inflammations, such as peritonitis and pericarditis, are rarely, if ever, due to this cause, is entitled to some weight; but it might conceal a fallacy, as we are not entitled to assume that the various tissues of the body which are analogous in structure necessarily obey precisely the same pathological laws. It is, of course, open to us to assume that in many cases exposure is only the exciting cause, and that the predisposition, whether rheumatic, tubercular, or other, was there before. That this is sometimes the case is most likely, but the fact upon which I wish to insist, and which my records seem to warrant, is that in apparently healthy people exposure and cold are frequently followed by an attack of acute pleurisy.

As regards the influence of rheumatism, I have not found pleurisy specially frequent in rheumatic subjects. Of my thirty-five cases only one had had rheumatic fever, and only two of the remainder had symptoms of rheumatism. When we think of the great frequency of rheumatism in the north of Ireland, this number seems to afford only a slight foundation upon which to found a causal relation between the two diseases. Another test that may be employed is to inquire whether pleurisy and valvular disease of the heart are often associated. On looking over my cases I find that in no instance is the presence of heart disease recorded. On the whole, therefore, while I am not disposed to ignore the influence of rheumatism, I have no facts to indicate that it is a frequent cause of pleurisy, and the presumption seems the other way. The question of the influence of tuberculosis in the causation of acute pleurisy is a much more important and difficult one. Dr. Barrs of Leeds recently contributed an important paper to the *British Medical Journal* with the view of showing that a very large number of cases of simple pleural effusion are really of tubercular origin. He inquired into the after-history of seventy-four cases of simple pleural effusion, and found that within five years thirty-two of these were dead, twenty-five were living, and seventeen could not be traced. Of the thirty-two who were dead at the time of inquiry fourteen died of phthisis, four died of other tubercular affections, and several of the remainder succumbed to some pulmonary affection. Putting aside the cases that could not be traced, we have the startling fact that of a series of cases of simple pleural effusion apparently recovered from more than one-half died within five years, and that the majority died of some tuberculous disease. It is needless to point out that if these facts are fairly typical and should be corroborated by a wider experience, the ultimate prognosis in simple pleural effusion, so far from being, as it is now, commonly regarded distinctly favourable, would become most grave. My cases are unfortunately for the most part too recent to enable me to say much about their ultimate history, but they may nevertheless afford some guidence towards the elucidation of this very grave problem. Thus, of thirty-five cases there were only two instances of a family history of tubercle, and only three instances of pulmonary hæmorrhage. As to how many of the thirty-five cases were probably tubercular I should find it difficult to say precisely, many of the cases being still in progress, and in some the presence of tubercle being suspected, but not absolutely certain. My impression is that the association of tubercle and pleural effusion is commoner than we have been in the habit of believing, but my records would fall far short of warranting the very alarming conclusions of Dr. Barrs. The point which he has raised is one of extreme interest and importance, and it is to be hoped that it will be sifted to the very bottom. If a patient who has had an attack of acute pleurisy subsequently develops tuberculosis, the question arises whether the pleurisy was originally of a tubercular character. Dr. Barrs says that "he sees no reason to doubt that, if a pleuritic effusion is followed by phthisis, the effusion itself was in the first instance of a tuberculous origin." This does not seem to me to be a tenable position. All my knowledge of pulmonary phthisis inclines me to the belief that if a lung be left collapsed and inexpansile as the result of pleural effusion it is very likely to become the seat of tuberculosis, and that the development of tuberculosis under such circumstances is no proof that the underlying process was tubercular from the first. While the evidence at present at my disposal does not warrant the conclusion that ordinary pleural effusion is commonly followed by tuberculosis, I must admit that in dealing with the great number of cases of pulmonary phthisis which come under observation I have been more and more impressed by the frequency with which pleurisy is found as an antecedent condition. This is a fact which cannot be ignored, and of which the adherents of Dr. Barrs' doctrine are entitled to make the most.



(To be concluded.)

THE FILTRATION OF URINE THROUGH EARTH.

BY F. B. WELLS, M.B. LOND.

I AM permitted by the kindness of Dr. Poore to place on record the results of a series of interesting experiments which have been made under his direction relating to the

FIG. 1.

slow filtration of urine through earth. A conical metal vessel, capable of containing about 40 lb. of dry earth,

Digitized by Google

and perforated at the apex, was used as a filter, and to this was added day by day an amount of urine averaging about half a pint. In the first three experiments, made between July, 1890, and February, 1891, fifty-nine separate analyses were made of the urine committed to the filters, involving the estimation of urea, sodium chloride, organic and mineral residues, and in subsequent experiments the averages of these analyses have been regarded as sufficiently accurate for purposes of comparison between urine and filtrate. The experiments are arranged in four divisions:—(1) Experiments made with mould from Gower-street; (2) experiments made with mould from Brondesbury; (3) experiments made with mould that had been previously used; (4) experiments made with the application of heat to the filter.

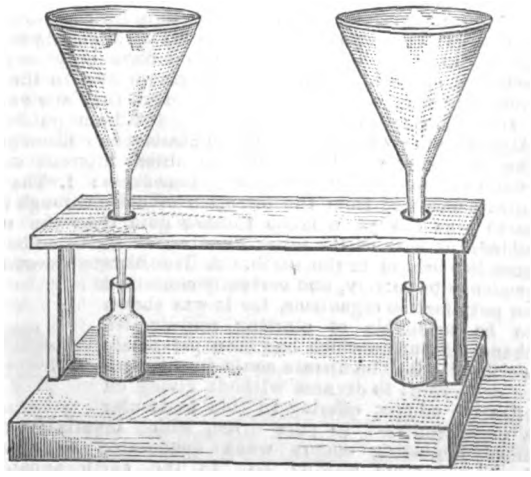
Of the first experiment, which has already been alluded to in a footnote to a presidential address delivered by Dr. Poore to the Sanitary Congress at Brighton, 1890, the following results were obtained. Two hundred ounces of urine were added to the filter, of which 73 ounces appeared as filtrate, the remaining 127 ounces representing what was lost by evaporation *plus* what remained in the filter. The average specific gravity of the urine was 1021·4, that of the filtrate 1011. The total solids of the urine averaged 4·44 grammes per cent., of which 3·45 per cent. were organic and 0·99 per cent. inorganic, while the total solids of the filtrate averaged 1·78 grammes per cent., of which 1·069 was organic and 0·710 inorganic. The chlorides in the urine averaged 1·09 grammes per cent., and in the filtrate 0·67 gramme per cent. The total solids of the urine added would be nearly 9 ounces, and the total solids of filtrate obtained about 1½ oz., so that 7⅞ oz. of solid residue were left in the filter. The appropriation of these 7⅞ oz. of residue by the filter will be again referred to.

The surface of the filter, when the nose was closely applied, smelt distinctly ammoniacal; but the filtrate, although of deep colour, could be evaporated to dryness without offensive smell. The filtrate showed no tendency to putrefy, nor did a few drops of it, added to sterilised urine in a tube, set up putrefaction. Next as to the experiments made with a different humus, and two of which were conducted in the garden at Brondesbury. I shall consider these two together, performed as they were with similar mould under similar conditions. In all 570 ounces of urine were added to the filters in equal additions of 10 ounces daily. Of this 228 ounces have been recovered as filtrate. The average specific gravity of the urine was 1020·3, and of the filtrate 1006. The urine contained an average 2·34 grammes per cent. of urea; the filtrate 0·15 gramme per cent., an amount which, allowing for possible error in the hypobromite method of estimation, may be disregarded. The average chlorides of the urine amounted to 1·35 grammes per cent., and of the filtrate to 0·33 gramme per cent., or of about 14 oz. (13·9) of urea added to the filter, 12½ (12·3) oz. did not appear in the filtrate, and of 8 oz. (8·03) of chloride added 6½ oz. (6·6) were unaccounted for. Nor do these results represent the best that have been obtained. Thus, in the last experiment made at Brondesbury, the first pint and a half of filtrate was almost colourless, of specific gravity 1003, chlorides 0·2 gramme per cent., and urea 0·13 gramme per cent.—an amount which, as already pointed out, may be disregarded.

None of the filtrates, after standing for weeks exposed to the air, underwent any putrefactive change, nor did any of them give off offensive smell when evaporated to dryness. In colour they have varied from the almost colourless filtrate above to a yellow or deep reddish-brown. In order to ascertain whether the colouring matter was of a urinary nature, part of the filtrate obtained from the first experiment was sent to Dr. MacMunn of Wolverhampton, who kindly examined it, and has furnished the following report of his examination:—

Colour.—A deep yellow, with orange tinge by gaslight, brownish tint by daylight.

Spectroscopic examination.—A layer 40 mm. deep absorbed a little of violet end of spectrum. No detached band in any depth. With HNO_3: No band; colour diminished. With H_2SO_4 in abundance: Colour almost discharged. By Jaffé's test (HCl and bleaching salt): Colour discharged. With NaHO: A precipitate carrying down all colouring matter; filtrate clear, showing no bands; some ammonia set free. With $NH_4OH + ZnCl_2$: Brownish precipitate; filtrate clear, and gives no fluorescence.



Result.—A total absence of normal urinary pigment and chromogen—that is, no urobilin, no indican, &c. The colour is probably due to the presence of some humus substance derived from the earth through which it has been filtered.

Now I will turn to the third group of experiments, those made with mould that had been previously used, an interval of five months having elapsed, during which the mould had remained intact. One hundred and nine ounces of urine were added, of average specific gravity 1024·3, with the following percentage analysis:—Urea, 2·6 grammes; chlorides, 1·2 grammes; residue, 5·48 grammes, being organic 4·12, mineral 1·35. Twenty-four ounces of filtrate were recaptured, of a uniform specific gravity 1035, with urea 0·2 gramme per cent. Thus the power of the filter to change the urea is as great as ever. Of chlorides there were 1·5 per cent., and residue 6·07 per cent., being organic 3·37 and mineral 2·70 per cent.—that is, the mineral residue of the filtrate is exactly double the amount of that in the urine; and it is evidently not due to chlorides, the respective average percentages being—urine, 1·2 grammes; filtrate 1·55 grammes. It seems probable that the 7⅞ oz. of residue left in the filter during the five months' interval has, to a great extent, nitrified and become soluble. Given an ammoniacal solution and garden soil, we have the readiest means of inducing nitrification. And, testing the filtrate qualitatively with ferrous sulphate and sulphuric acid, there is abundant evidence of the presence of nitrates. Experiments such as these—tedious, and extending over a long period—are necessarily incomplete, and it yet remains quantitatively to estimate the nitrates present.

[A new series of experiments has been instituted, in which this obvious omission will be rectified by a complete analysis of the mould at the beginning and end of the experiment.]

I shall refer but briefly to the experiments that have been made with the aid of heat roughly applied by means of a "Fletcher's burner" to the exterior of the filter, since these are, at present, the most incomplete of all the experiments made. The object has here been to maintain the mould at such a temperature as is best suited to the micro-organisms of the earth concerned in nitrification—a temperature of about 40° centigrade. In the first of these experiments, and the only one to which reference will be made, when seventy ounces of urine had been added, two ounces of filtrate were

FIG. 2.

obtained. This filtrate was of specific gravity 1002, contained no urea, and had a percentage residue of 0·54 gramme, being 0·34 organic and 0·2 mineral; 10 cubic centimetres of it yielded no appreciable evidence of chlorides. The average percentage analysis of the urine added was:—Urea, 2·2 grammes; chlorides, 1·4 grammes; residue, 4·9 grammes; of which 2·66 were organic and 1·24 mineral. Then from defect in the apparatus the mould became overheated and the filter inefficient.

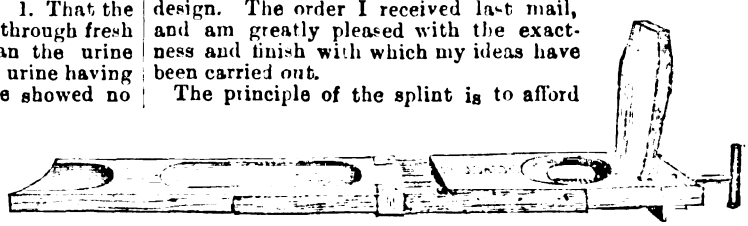
[In the new series of experiments the earth will be maintained at (presumably) an optimum temperature by an incubator which has been specially constructed.]

Digitized by Google

It will be convenient here to describe an experiment that was made to ascertain what difference in results might obtain from a water and a urine filtration through mould. Two glass funnels were employed, each of capacity about four pints, and were filled with mould. To one was added during a period of twenty days, in regular amounts, an ounce and a half of tap water, and to the other an equal amount of urine. Rye grass seed was, moreover, sown on each filter surface. The water filter produced seven ounces and a half of filtrate, and developed an excellent crop of rye grass; the urine filter produced five ounces and a half of filtrate and no grass. The daily addition of *water* was followed, after the filtrate had once commenced to appear, by an almost *immediate* dropping of filtrate; *the urine tarried much longer in the mould.* That no grass would grow on the mould to which urine was being daily added was to be expected, ordinary urine being about twenty times too strong for plant culture. The filtrate obtained from the urine filter was odourless, clear, of pale yellow colour, specific gravity 1006, containing about 0·5 gramme per cent. of urea (? or other nitrogenous bodies), and yielding no offensive smell on evaporation to dryness. The water filtrate was of faint yellow colour, and of specific gravity 1000. Finally, a few experiments were made in which grass seed or plants were used in connexion with the mould from the filters. In May, 1891, a mixture of equal parts of mould that had been used for filtration, and one-half of which had moreover been sterilised by heat, was sent to Andover, and there twenty cuttings of common yellow calceolaria were placed in pots as follows: Ten in garden soil from the garden at Andover; ten in the London mould. The pots were placed in the open. Here is the result: In the ten pots of Andover soil the calceolarias had done fairly well, and each pot had grown an abundant crop of weeds. In the ten pots of London earth the calceolarias were all dead, and there was not a single weed visible. They were the embodiment of absolute barrenness. Corresponding portions of mould were used for urine filtration, and yielded a filtrate of specific gravity 1041, with a large percentage of urea. In no case has grass grown on the surface of a filter in use. But on mould that has remained for several months exposed to the light and air in the garden after usage in the filters grass has been cultivated most readily, yielding a better crop than that produced by unused mould.

Brondesbury, Oct., 1889.

Note by DR. POORE.—Although these experiments are manifestly incomplete in some particulars, I have advised Mr. Wells to publish them and to trust to a future opportunity for amplifying and completing the statements above made. The power of the earth to deal with organic matter is one of those things of which we have only recently obtained an insight, an insight which we owe to the new science of bacteriology. I am not aware that any experiments similar to the above have yet been published. Although the experiments are tentative and incomplete, the results obtained are of undoubted interest, and I would venture to call attention to four facts: 1. That the filtrate obtained from the filtration of urine through fresh earth was always a much thinner fluid than the urine added, the bulk of the solids dissolved in the urine having been left behind in the earth. 2. The filtrate showed no tendency to putrefy, and certainly contained no putrefactive organisms, for it was shown to be incapable of starting putrefactive changes in urine which had been previously sterilised. 3. The filtrate could in all cases be evaporated to dryness without giving off offensive odours, offering in this particular a great contrast to pure urine, which invariably emits most disgusting odours when evaporated to dryness. 4. The organic residue left in the earth apparently underwent nitrification in course of time, but it was noteworthy that earth which had been used for the filtration of relatively a very large amount of urine was in all cases barren until after it had been exposed to air and rain. After such exposure, however, its fertility appeared to be of a high order. The practical importance of this matter to sanitarians and agriculturists is very great. In London, with its 4,000,000 inhabitants, it is probable that 10,000,000 pints of urine are daily run to waste, and it must be remembered that these 10,000,000 pints contain about 200 tons weight of most valuable manure.



Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

TREATMENT OF FRACTURES OF TIBIA—MORE ESPECIALLY COMPOUND—BY MEANS OF SCREW EXTENSION.

BY G. R. MOORE GRAHAM, L.K.Q.C.P.I., &c.

SOME short time back I had occasion to be summoned to an accident that had occurred to a member of a travelling circus troupe, an acrobat named V. V——, who, whilst rehearsing previous to his evening performance, missed his hold on the trapeze and fell with great violence against the sharp edge of the stage, injuring, I was informed, his left leg. Upon making an examination I discovered that the left tibia had sustained a severe compound oblique fracture at the junction of the middle and lower thirds, and owing to the muscular development the upper fragment was considerably protruded through the skin. Chloroform having been administered, a reduction was made, and by means of the orthodox weight over the raised foot of the bed, sandbags, &c., I endeavoured to keep the fragments in apposition, but invariably with a negative result. As the condition of the patient and injured limb was anything but assuring, I felt it was necessary to adopt other means if the leg was to be saved, with the result that I designed the splint I am about to describe (see engraving), and had it roughly made by Japanese mechanics. Upon applying it I was gratified to find that the fragments, when once placed in apposition, never moved; also that the wound began to heal rapidly, and the patient expressed himself as greatly relieved and very comfortable, which satisfactory state of affairs continued. In three weeks' time the splint, having performed its duty, was removed; the wound had almost healed, and the fragments were well in position and uniting. The limb was put up in plaster-of-Paris, and the patient allowed to move about on crutches. In a short time he removed to Yokohama, where I am led to understand Dr. Stuart Eldridge, of that place, removed the plaster, and the wound not having quite healed he passed a probe and discovered a small piece of dead bone, which he removed, and which was shown to me at a later period. After this the wound healed entirely, and, according to latest accounts, the patient is following his usual occupation in India, and suffering no inconvenience. I might also state that, although a piece of necrosed bone came away, there was no shortening of the limb whatever. The original splint, roughly made, I sent to Messrs. Arnold and Sons, asking them to make the same according to the design. The order I received last mail, and am greatly pleased with the exactness and finish with which my ideas have been carried out.

The principle of the splint is to afford extension by means of a long screw fitted with a handle applied to the posterior surface of an ordinary leg-splint with foot piece, the splint being divided at the seat of fracture, as shown in the engraving; by means of the screw the divided segments are forced apart, and the power is so great that you can overcome the greatest amount of muscular contraction to a nicety. The splint being applied closed to the injured limb, the foot and lower fragment are securely bandaged to the lower segment of the splint, the upper fragment also being bandaged to the upper segment, the seat of fracture being left uncovered; by means of the handle the screw forces apart the divided splint and draws the fractured bone into place, which being accomplished, the limb is left with that amount of extension until the process of repair is nearly finished.

Digitized by Google

Another advantage is the facility with which, if the fracture is compound, the wound is dressed, causing no pain or discomfort to the patient and no inconvenience or trouble to the attendant, also no chance of the fragments becoming displaced. I trust that I have not infringed any existing rights, but plead ignorance and distance from the *fons et origo* of information if I have done so.

P.S.—I quote this case as one of several, but this being the first and worst treated by this splint.

GANGRENE OF LUNG FOLLOWING PNEUMONIA IN A CHILD TWENTY-ONE MONTHS OLD.

BY WALTER B. DE JERSEY, B.A., M.B, B.C. CANTAB.,
SENIOR RESIDENT MEDICAL OFFICER, EVELINA HOSPITAL FOR SICK CHILDREN.

H. S.——, aged twenty-one months, was admitted into the Evelina Hospital for Sick Children on Nov. 3rd, 1891, under the care of Dr. Frederick Taylor, to whom I am indebted for permission to publish the case. There was a history of phthisis on both sides of the family. The infant was fat and healthy till its present illness, eight weeks previous to admission, when he first became feverish. A week later he was seen by a doctor, who said he had bronchitis, and ordered poultices to the chest. Five weeks before admission the patient became much worse, with severe dyspnœa, loss of appetite, and fever. Bowels confined. Child apathetic.—Oct. 30th: Lips blue, face of a "yellowish white colour," and cough severe; alæ nasi working; no expectoration appeared externally; no fetor of breath noticed. On admission a fairly well nourished child; face pale; alæ nasi working; no herpes. Temperature 101·6° F.; pulse 146; respiration 36. Markedly rachitic; mouth and throat healthy; tongue furred; breath not offensive. Wooden dulness over the whole of the left chest, except near spine, where there was rather more resonance. Blowing breathing in front from apex to nipple, and behind down to middle of scapula; only very faint distant breath sounds elsewhere; no crepitations or moist sounds. On right side a few fine crepitations at base, otherwise healthy. Heart sounds normal, apex beat not displaced. Nothing abnormal in abdomen. The left side of chest a quarter of an inch larger than right. An exploring needle was inserted into the left chest, first, in the sixth space in the mid-axillary line; second, in the sixth space external to the angle of the scapula. In each case pus was withdrawn, but in neither could a syringeful be obtained. Considering the physical signs and the pus obtained a sufficient warrant, I made (in Dr. Taylor's absence) an incision in the sixth space between the post- and mid-axillary lines. About a drachm of pus escaped with an extremely fetid odour; on inserting the finger between the ribs soft friable lung, which easily broke down, could be felt. The temperature gradually fell after the operation to 98° F.; pulse 124; respiration 36.—Nov. 4th: Child looking very ill. Pulse 130, weak; respiration 50; temperature 103 F. Dressed; thin brown discharge, very offensive odour. — 5th: Face pale, child apathetic all day; some diarrhœa and vomiting, both very offensive. Dressed; discharge as before. Dulness wooden over the whole of the left lung. No breath sounds heard.—6th: Temperature rose all day after being down yesterday; vomiting less; no diarrhœa; child restless till this evening; dying quietly at 6.30 P.M. Breath for the last forty-eight hours very offensive. Treatment, quinine and stimulants.

Necropsy, thirty-one hours after death.—Left lung solid, tubes widely dilated and thickened, containing a large amount of pus. Scattered patches of gangrene all over lung, the whole very fetid. Pleura adherent firmly all over. Some bronchitis in right lung; nothing else abnormal in any part of the body. No tubercles found anywhere.

Remarks.—The above case is interesting on two grounds: first, the fact of gangrene of lung occurring in so young a child after what was in all probability pneumonia; second, the difficulty in the diagnosis. At the post-mortem examination no disease of the heart or any of its valves was present, and there were no clots, ante- or post-mortem, in any of its chambers. The pulmonary artery and its branches showed no signs of plugging. The cause of the condition cannot then be put down to simple embolism; again, septic embolism may likewise be dismissed, no disease of ear or any other septic origin being found. Though the bronchial tubes were much dilated, none of them showed any ulceration in their interior; all, however, having their walls much infiltrated. It is usual to find in pneumonia and broncho-pneumonia in children thickening of the tubes and septa to a greater or less degree, the inflammation affecting not only the alveoli, but also the interalveolar tissue and the tubes. An acute inflammation would then account for this thickening, and the dilatation of the tubes would easily occur in their softened condition by the efforts of expiration and inspiration, and by coughing; the lung itself, unable to withstand the acute attack so widely spread, becoming gangrenous. Though very disorganised, there was little doubt, on careful examination, that the lung had been in a pneumonic condition previously. With reference to the difficulty of diagnosis, all the signs of fluid were present except displacement of heart. It was found post-mortem that a needle would have withdrawn pus from the tubes at almost any point on the left side at which it was inserted.

ENTERIC FEVER IN A CHILD FOUR MONTHS AND A HALF OLD.

BY JOHN G. OGLE, M.B.

IN connexion with the case recorded by Dr. Fuller in THE LANCET of Nov. 7th, the following notes will be interesting:—

The body of Metha Amanda D——, aged four months and fourteen days, was brought to St. Bartholomew's Hospital on Sept. 17th, 1889, death having taken place on the way to the hospital. The history elicited from the mother at the inquest was as follows:—The child, one of twins, had been healthy from birth. She had been fed on condensed milk. On Sept. 11th she was vaccinated, and since then had been vomiting, but did not appear to be ill. On Sept. 17th the mother went to her work in the morning, leaving the child, apparently well, in the charge of a friend; in the evening, on her return, the child was in the mortuary at St. Bartholomew's Hospital. The friend stated that on the morning of the 17th the child was very fretful and vomited frequently; she got worse in the afternoon, and died on the way to the hospital. The bowels acted on the 17th, and the motion was solid and lemon-coloured.

Post-mortem Examination.—The body was fairly nourished, but there were marked evidences of rickets. No signs of violence were found. The vertex of the brain was somewhat ecchymosed, and the left lateral ventricle contained a considerable excess of fluid. The intestines presented the appearances typical of enteric fever. The Peyer's patches were swollen and reticulated, and many of them, especially in the lower part of the ileum, were converted into ragged ulcers. The first ulcer occurred about twenty-four inches from the stomach, and they were of circular shape, and about four inches apart in the jejunum. In the ileum the ulcers were much more numerous, and assumed an oval form, with the long axis in the long axis of the intestine. The mucous membrane of the colon was covered with minute inflamed solitary glands, which were ulcerated in the ascending portion. There was no peritonitis or perforation. The stomach was empty and the mucous membrane healthy. The mesenteric glands were enlarged. The spleen was large and soft. Murchison makes mention of three cases in younger infants—viz., eight days old, fifteen days old, and in a fœtus of seven months.

Oxford.

FRACTURE OF THE NASAL SEPTUM.

BY W. T. CLEGG, L.R.C.P. & M.R.C.S.

DURING the past year two cases of this injury have come under my notice. In both the cartilage of the septum was displaced so as to occlude the left nostril. Both complained that the right ala nasi being unsupported fell in when an inspiration was taken with the mouth closed, and acted like a valve, making nasal breathing an impossibility. It was to remedy this that both patients consulted me. Now all mention of this is omitted in articles treating the subject, yet it is the principal difficulty to be dealt with. In the first case, by making four cross cuts through the cartilage eight triangles were formed, and these were separately fractured at their base. The septum could then be pushed into place, and the nostril plugged to support it. At the end of three weeks the result was perfect. I have lost sight of the patient since, and so cannot say whether the good result was permanent, but I have no reason to doubt it. The second case has not yet come up for treatment.

A CASE OF ACUTE ORCHITIS FOLLOWING INFLUENZA.

BY J. W. HARRIS, L.R.C.P. LOND., M.R.C.S., &c.

THE following case may be of interest during the present epidemic of influenza:—

On Nov. 26th I was called to see a man, G—— W——, aged sixty-seven, a widower. He was complaining of "pains all over," more especially in the back, head, and back of eyes. Slight cough. Temperature 103·2°; pulse 120. Tongue slightly furred; bowels open. I gave him twenty grains of salicylate of soda every four hours, and he gradually lost his fever and pain. On Dec. 1st, on visiting him, I found him complaining of pain, tenderness, heat, swelling, and redness of the left testicle. Temperature 102°. I gave him an aperient and a saline mixture, with one grain of potassio-tartrate of antimony, every four hours, and he gradually recovered, and on Dec. 21st he was down stairs.

There being an epidemic of the so-called "influenza" in the town, I looked upon this case of one of acute orchitis following influenza. As the patient never got out of bed, had no trouble with his urine, and could account for the swelling in no way, and orchitis coming on as it does after mumps (metastasis), the case seems to me somewhat obscure. I should be glad to know if any of the readers of THE LANCET have met with a similar one.

UNIVERSITY COLLEGE HOSPITAL

FIFTY CONSECUTIVE MAJOR AMPUTATIONS.

(Under the care of Mr. A. E. BARKER.)

THE following fifty consecutive major amputations are here tabulated as a small contribution to the statistics of a very interesting subject. They form an unbroken series, no amputation performed by Mr. Barker since 1876 being omitted except those smaller operations for the removal of parts of the hand and foot below the wrist-joint and tarsus, all of which did well.

Double amputations, of which there were three, are entered as one operation. One patient required reamputation in the thigh, after removal of the leg two years before, for gangrene, due to alcoholic arteritis. These two operations are counted separately. In one amputation in the middle of the thigh, the rest of the femur up to its head was subsequently removed by a separate operation, making this case practically one of exarticulation at the hip. This is only put down as one case.

	Position in thirds.		Disease. Recov.	Disease. Died.	Injury. Recov. Prim.	Injury. Recov. Sec.	Injury. Died.
Thigh	Upper	1	....	—	—	.... —	1 —

	Lower	7	....	4	1	 2	1 —
Wrist-joint		2	....	—	—	 1	1 —
Total		50	....	26	3	 20	4 1

From this table it will be seen that forty-six patients recovered from operation and four died.

CASES 3, 19, 30, and 49.—The cause of death in each was as follows:—

CASE 3.—A man aged forty-two had tubercular abscesses about the wrist-joint for four months, with sinuses, and was greatly broken down in health. An attempt to excise the wrist failed, and a fortnight later amputation was performed in the lower third of the forearm. The wound showed feeble power of healing and the lungs were evidently affected with tubercle. He died of asthenia due to pulmonary tuberculosis on the twenty-first day. At the post-mortem examination there were twenty-four ounces of bloody serum in the left pleura; the right lung contained an enormous cavity, with surrounding tubercular consolidation; in the left lung there was tubercular consolidation of all the upper lobe, with a few moist cavities.

CASE 19 was that of a man aged twenty-eight, whose legs had been run over on the railway, the right being crushed to pulp up to the middle of the leg, the left nearly to the knee. Double amputation through thigh and below knee followed two hours and a half after the accident. Soon after the pulse became very feeble and frequent, and the patient steadily sank and died forty hours later of shock. The temperature after operation was 96°; then only rose to 98·6°, and then fell, until just before death it was 97·6°. At the post-mortem examination nothing special was found, except slight "fat embolism" in the lung.

CASE 30 was amputated above the knee for epithelioma of the leg. After the first week the patient did not do well. He said he had for a long time been subject to gout, and he had after the operation attacks like gout in the stump, which showed little power of repair. The temperature was usually below 100°, but touched 101·8° on two or three occasions. In the fourth week he began to fail, and he died of asthenia on the twenty-ninth day after the operation. There was a suspicion of trismus not long before death.

CASE 49 was that of a lad of eighteen in the last stage of exhaustion. He had more than a year before had acute necrosis of the left femur, which resulted in large open abscesses. Amputation was urged, but refused, and these abscesses continued to discharge freely up to the last. Eleven months after the first he had a second attack of acute necrosis, this time in the right shoulder, with suppuration along the whole humerus, large abscesses, and great prostration. Later the head of the humerus came away with profuse suppuration. Amputation was proposed, and was refused for a considerable time. Then amputation was agreed to, but the patient was too weak to bear it, and it was put off. Finally he was thought to have improved a very little, and the soft parts were simply divided which held the wasted arm to the shoulder. Little or no blood was lost, and all was rapidly and simply done. He was dressed daily, and the wound cleaned. He gained some strength for the first week, then he began to fail again. Another large abscess formed over the scapula. He died of asthenia on the seventeenth day after amputation

Of these four deaths, only one at the most can be credited directly to the operation. Cases 3 and 49 plainly died from the exhaustion of the disease for which the amputations had been done three weeks before. The operations were only undertaken as their last chance, and, at any rate, to rid them of limbs which were practically rotting away. Case 19 plainly died of the shock of a terrible railway injury which carried away both his legs. But death in Case 30 may fairly be credited to the operation itself, though the cause of the gradual failure afterwards was always obscure. Possibly more judgment would have been shown in leaving Cases 3 and 49 alone as too far gone to be saved. But, on the other hand, the surgeon is anxious to relieve a patient, even in advanced phthisis, of a member which is a source of untold suffering, if it can be done by so simple a procedure as amputation above the wrist; or, again, if the arm is only hanging on to the shoulder by some thin strips of tissue it seems cruel not to remove the rotting mass below by a few strokes of a scalpel if the patient can bear a few minutes under chloroform. On these grounds the two cases were treated, but the original disease carried them off some weeks later.

If we assume that only one of the four died of the effects of operation the mortality on the whole series is brought very low indeed. Two per cent. of deaths in a series which contain over 30 per cent. of amputations above the knee and three or four double amputations is a decided advance on earlier times. But this is not the only improvement. The

Digitized by Google

mode in which a large number of this series of amputations have healed shows too how we are advancing. Many cases, more especially the latest, have healed absolutely in a week or ten days under one dressing and without any drainage of any kind, the temperature remaining normal all the time. Suppuration, with high temperature of course occurred in several cases, especially among the earlier ones. This is only to be expected where all kinds of injuries and disease are treated by amputation close to the damaged part. But suppuration was not very serious in any case. Other unfavourable sequelæ of amputation were very rarely seen. Secondary hæmorrhage occurred in one case only; necrosis, to a very small extent, of the end of the bone occurred in one case under observation, and to a large extent in another case, months after the patient had left the hospital with a sinus. This sequestrum was removed at another hospital. Perhaps slight exfoliation occurred in a third case There is no note of it in the registrar's record, but Mr. Barker has some recollection of seeing the woman as an out-patient, and removing a flake of bone from a sinus. In one case the portion of the os calcis left in the flap of a Pirogoff's amputation had to be removed on the seventeenth day as suppuration had loosened it.

One of the most troublesome sequelæ of the operation chiefly seen among the earlier cases was carbolic intoxication with fever and irritation of the skin. This is not noted among the last half or so of the series, which were mostly treated with dry dressings. It is highly probable that the blush seen in the only case set down as affected with erysipelas was in reality nothing but a carbolic rash. In this case a slight blush appeared about the knee on the ninth day after a Pirogoff's amputation, and in the notes we find "carboluria" on the eighth day. Pyæmia and septicæmia were never seen among the whole series. Erysipelas is noted in the registrar's record as present in one case, that just alluded to. In another case a rash appeared on the buttock where the thigh had been amputated. This was not regarded by the registrar as erysipelatous, and is not entered in the notes as such. It is just possible that it may have been, but the patient's general condition was excellent throughout except for high temperature. It may also have been a carbolic rash.

The dressings employed in this series were as follows:—In the first ten cases the spray was used and the old carbolic gauze was packed round the stump as usual. In the next fifteen or so of cases carbolic oil on lint was the usual application to the wound after careful washing with carbolic lotion. This lint was supported by an abundant packing of wool. The last twenty-five or so of cases were put up in one or other form of dry antiseptic dressing with or without drainage, the dressing in almost every case being salicylic wool, the sutures silk, latterly exclusively so. This last dressing has given by far the best results, such amputations through knee-joint and thigh in several cases healing perfectly under the first dressing without any drainage. There were twenty-six amputations for disease, with three deaths, and twenty-four for injury, with one death.

Remarks, by Mr. BARKER.—So much has been said and written of late about the insanitary state of our large metropolitan hospitals and the consequent high mortality of the major operations performed in them, that it is pleasant as well as important to record anything which may show such a charge to be unfounded at the present day. Amputations have usually been considered a fair test of hospital efficiency. If I, during my first fifteen years of duty at one of our busiest institutions, and dealing with cases of all kinds, the healthy with the unhealthy, the temperate with the drunken and dissolute, without any special selection, have only had at the very highest a mortality on my major amputations of 8 per cent., such a charge against general hospitals is certainly not justified. But if, as is shown by a study of the above, the real mortality from these operations themselves is, strictly speaking, only 2 per cent., it may be claimed that no institution for the reception of the sick, whether private "nursing home" or special public hospital, can show much better results. The careful study of these fifty cases has been most useful and instructive to me. The errors committed in my earlier cases have been seen to disappear one by one in the latter part of the series, and in such a way as to justify the hope that when my next series of fifty major amputations of limbs is completed, it may show a still further improvement upon the older methods. This improvement will be based on greater judgment in the exclusion of hopeless cases, a sounder knowledge of the conditions which govern the repair of wounds, and greater skill in the carrying out of the details of treatment which promote the latter.

RADCLIFFE INFIRMARY, OXFORD.

INTERESTING SURGICAL CASES RECENTLY UNDER TREATMENT IN THE WARDS.

(Under the care of Mr. H. P. SYMONDS.)

IT is interesting to note with regard to this case the short duration of the discharge from the ear before the more serious symptoms developed which led to the performance of the operation; also the apparent absence at both operations of any lesion sufficient to account for the symptoms, and the great relief afforded by the operations. There does not appear to have been sufficient proof forthcoming that the abscess in the neck was dependent on a suppurating thrombus of the internal jugular vein, which again is negatived by the absence of important symptoms. We published last year two cases which may be read with advantage in connexion with this case.[1] Case 2 is an example of the successful removal of a fibroid uterus after abdominal section and the extra-peritoneal treatment of the pedicle. As we recently pointed out, this method is the one which has been found to give the best results when it is necessary to perform extirpation for this disease.[2] Case 3: There can be no question of the propriety of surgical interference in this case, the presence of pus, with the duration of the case, making operation imperative. The occurrence of localised suppuration in perityphlitis is seen in a very small percentage of the patients applying for treatment in our hospitals, and it is not often that the appendix is so readily seen and treated as it was at this operation. For the following notes we are indebted to Mr. W. J. Turrell, M.B. Oxon.

Trephining Right Lateral Sinus.—W. H——, aged thirty-eight, was admitted on Feb. 2nd, 1891, said to have been ill eleven weeks with influenza and acute tonsillitis. For the last three weeks he had been much worse, suffering from intense cephalalgia. During the past week he had been delirious, but not violent. He had a discharge from his ear for a fortnight before admission, and had had his membrana tympani incised by Mr. Maisey of Charlbury. On admission, he was delirious, but not violent, the delirium being of an active muttering type. There were no localising symptoms of any cranial suppuration. No facial paralysis, no strabismus, the pupils were equal and reacted to light. Knee-jerks normal. Temperature 100° F. There was a red fluctuating swelling on the right side of the neck in the line of the internal jugular vein. On the night of admission, the patient being under the influence of methylene, Mr. Symonds trephined the lateral sinus on the right side with a half-inch trephine; no pus exuded, but there was a flow of dark venous blood, which was readily arrested by plugging with iodoform gauze. The abscess in line with the internal jugular vein was afterwards opened. The wounds rapidly healed, but no improvement took place in the patient's mental condition; on the contrary, he became violent, and had to be quieted by hypodermic injections of hyoscine, 1-150th to 1-100th of a grain. These injections never failed to induce sleep, and on awakening the patient was always more rational. He lost flesh rather rapidly and became very much weaker. On Feb. 24th he seemed rather better, took his food well, and was sensible for most of the day. On the 25th the patient was put under the influence of chloroform, and Mr. Symonds gouged through the lower part of the mastoid process, but did not find any pus. After this operation the patient was quite rational, took his food well, and gave no trouble. On March 2nd he was moved into the general ward. On the 7th another abscess was noticed behind the right angle of the jaw. This was opened on the following day, and was found to be very deeply situated; counter-opening was required, and a drainage-tube inserted. The patient continued to be perfectly rational, took his food well, and rapidly put on flesh. He was discharged on March 25th cured, with the exception of a superficial granulating wound behind the right ear. Since leaving he has twice been up to the hospital in perfect health.

Hysterectomy.—Frances H——, aged thirty-seven, was admitted on Jan. 28th suffering from a fibroid tumour of the uterus, which caused increased flow of blood at the catamenial periods and considerable pain and discomfort. She first noticed the swelling in June, 1890, after her last confinement, which was a difficult one, the child being stillborn. She had been in the hospital in the autumn, but was then unwilling to undergo the proposed operation of oöphorectomy. On Feb. 3rd, the patient being under the influence of ether, Mr. Symonds made an incision about three inches long between the umbilicus and pubes in the middle line, and opened the peritoneum in the usual way; a small quantity of peritoneal fluid escaped. The tumour at once presented at the lower part of the wound, covered at the upper part by intestines; it was of irregular outline, its surface being studded with several small, very vascular, pedunculated fibroids. It was about the size of a double fist. Mr. Symonds first removed both ovaries and then determined to remove the uterus, which he did by dragging it out of the wound, applying a Koeberlé's serre-nœud round its base, inserting two Koeberlé's needles beneath the wire and then excising the mass, including uterus and fibroid. The peritoneum and edges of the wound were brought together round the stump, and a dressing of boracic powder and sal alembroth gauze applied. The duration of the operation was seventy minutes, and was followed by no marked collapse. On coming round from the anæsthetic the patient complained of great pain in her abdomen, which was relieved by one-sixth of a grain of morphia given hypodermically.

On Feb. 4th she had a good night, with five hours' sleep. Evening temperature 101·2°. On the second day after the operation the clamp was tightened half a turn, on the third day one turn. On the fifth day the wound was partially dressed, the deep dressing being powdered with boracic powder but not removed. On the sixth day (Feb. 9th) a little pleurisy developed on the right side; the ribs were strapped. On the seventh day the clamp was tightened one turn. On the eighth day it was tightened two turns On the ninth day (Feb. 12th) the wound, when dressed for the first time, appeared quite healthy. The clamp was tightened one turn twice daily. On the twelfth day (Feb. 15th) it was screwed up to the end. On the thirteenth day (Feb. 16th) the clamp was removed. On the fifteenth day (Feb. 18th) iron sulphate was dusted on the stump. On the sixteenth day the wound was dressed, a large slough cut away, and one of Koeberlé's needles removed. Wound dressed daily. The remaining needle was removed on Feb. 22nd (nineteenth day).

The wound gradually healed up from the bottom and she was discharged cured on March 28th. Since her discharge the patient has been up to the hospital several times, and is now in very good health and able to perform her household duties.

Perityphlitis: Excision of Vermiform Appendix.—A. M——, aged twelve, a well-nourished healthy-looking boy, was admitted on June 16th suffering from perityphlitis. He was quite well on Sunday, June 7th, but on the 8th thinks that he caught cold. On June 10th the patient first felt a darting pain in the right iliac fossa, and noticed a hard swelling there. It was then as big as when he was admitted. The pain was very severe, and kept him awake at night. On Sunday, June 14th, he saw Dr. Barnes of Wheatley, who sent him to this hospital.—June 17th: He did not sleep well last night, and the temperature was 101·4°. This morning 99°, lies quietly in bed, and does not appear to be in much pain. Tongue coated with white fur. There was a hard-tender swelling in the right iliac fossa, but the skin was not red. Pulse 96, low tension, regular; respiration 28, shallow. Bowels not open since admission.

June 18th (morning)—The patient seems much better to-day. The fullness in the right iliac fossa seems less, there is no redness of the skin, and no fluctuation, but it is very tender. He was very constipated, enemata bringing away large fæcal masses. After a consultation at twelve, the patient was anæsthetised and Mr. Symonds, as soon as the patient was fully under, obtained distinct fluctuation. He then made a slightly oblique incision, about two inches and a half long, commencing at the level of the anterior superior iliac spine, one inch and a half internal to it, going downwards and slightly inwards. Upon deepening the incision a quantity of very offensive pus of a dark greenish colour poured forth. Mr. Symonds without difficulty found the vermiform appendix, and seized the extremity of it with pressure forceps, which at once tore away owing to the rotten condition of the tissues. The forceps were then applied higher up, and above them an annular ligature was applied round the appendix, and the ends of the ligature being left long to hold by, the portion of the appendix beyond the ligature was removed. Two chromic gut sutures were next inserted above the annular ligature through the wall of the appendix one on either side, and after they had been separated in the usual manner their ends were tied together so as to form a "purse suture." The cavity was thoroughly douched out with boracic acid lotion, iodoform dusted over, and the wound plugged with iodoform gauze. The excised portion was found on examination to contain a well-marked ulcer, with a perforation about its centre.

The discharges came through the dressing the night of the operation, and the temperature rose to 100°. The wound was redressed with iodoform gauze. On the next day the patient said that he felt much better, and entirely free from pain. Temperature normal. The patient made an uninterrupted recovery; the wound was repacked nearly every day to ensure its healing from the bottom. There was no further rise of temperature. Bowels acted regularly. Patient was up at the end of a fortnight, and was discharged cured on July 18th, with the wound healed.

Medical Societies.

LONDON EPIDEMIOLOGICAL SOCIETY.

Famine and Disease.

A MEETING of this Society was held on Wednesday, Dec. 16th, Dr. J. Ewart, President, in the chair.

Sir WILLIAM MOORE, K.C.I.E., Q.H.P., read a paper on Famine. He commenced by mentioning some of the principal causes of famine, and remarked that he did not agree with what had been said by Mr. Danvers of the India Office, in his report on Famines in India—viz., that failure of the rains was not the usual cause. Want of means of communication intensifies famine. There may be plenty in one district and famine in another. When the rains fail the grass disappears and the water dries up, so that beasts of burden cannot be used to convey food to the people. This was sorely felt in the Rajpootana famine, as there was then no railway and not a good road throughout the country. The people therefore emigrated in search of food, passing in great streams to the north into the Punjaub, to the south to the Bombay Presidency, towards the west to the Indus, and east over the Aravelli mountains into Malwa and Central India. From the principality of Malwa alone it is estimated that one million of people emigrated, taking with them one and a half million of cattle. The anti-opiumists had said that the extending cultivation of opium in Malwa had caused the famine in the neighbouring province of Rajpootana. But the fact was that tens of thousands of human beings, and more cattle, found food in the opium growing province of Malwa. As war has its "couine" of famine, so famine has its result of disease. Ovid had vividly described famine, and Sir William Moore had seen the famine-stricken, emaciated, digging for roots and dying, as Ovid had described hundreds of years ago. The first result of famine was anæmia, which was combined with a peculiar apathy which prevented the famine-stricken caring for work. Sympathy with the famine-stricken had been diminished because it was found the people suffering from starvation would not work. This was the result of the ill-nourished brain, and of the constitutional apathy and belief in *nusseeb*, or fate, common to most orientals. But it was intensified by starvation, and the starving ought not to be blamed for their apathy more than they should be blamed for any other disease which starvation produces. Bowel complaint soon attacks the famine-stricken. This is especially the case in India, because the people there are from climate very liable to bowel complaints. Post-mortem examination had shown that changes of a fatty nature in the intestines resulted from starvation. But the primary cause of the bowel complaint was generally the articles the people used as food. These had been investigated by Sir W. Moore and Dr. G. King in Rajpootana, and

Digitized by Google

a list was published by the Government of India in one of Sir W. Moore's reports. In the Bombay Presidency the famine foods had been investigated by Brigade-Surgeons Gray and Lyon, and in the Madras Presidency by Dr. Shortt. They were barks and roots of trees, seeds of grapes, seeds of trees, wild fruits, the stalks of the American aloe, stalks of rushes, the refuse of *till* seeds after oil had been expressed, lizards, locusts, and various other things. During a famine, and especially after a famine, when the next rains set in, there is always an enormous increase of fever. The type of the fever varies in different countries and climates. After the Irish famine it was typhus fever. During and after the Rajasthan famine it was malarious. During the Bombay famine it was diagnosed as relapsing because the *spirillum Obermeiri* had been found in the blood of some of the sufferers. But if it is correct that relapsing fever depends upon the spirillum, it must be an infectious fever, and therefore was not caused by famine. The subject was important because it had been said the spirillum signified relapsing fever, and relapsing fever signified that the people were being allowed to die from want of food. It is questionable whether relapsing fever is a famine disease, for although it has sometimes prevailed when there was famine, famine has often occurred without relapsing fever. All fevers in the tropics have a tendency to assume the relapsing type—so much so that Dr. Lyon of the Bengal Service wrote a book, endeavouring to prove that all fevers are relapsing. Scurvy was very prevalent during famines; so was, as Sir William Moore regarded it, the allied disease beri-beri. He had seen a great deal of beri-beri, and had elsewhere given reasons for regarding it as a phase of scurvy. Others, however, have "gone in" for a beri-beri microbe, but have failed to explain why the microbe comes only, or at least chiefly, when certain environments prevail. During famines beri-beri often assumes the general œdematous form. But in one season of scarcity coming under the lecturer's cognisance serous effusion was limited to the abdomen, and numbers of famine people were tapped. Skin diseases become more common during famine. Go does *peenash*, or maggots in the nose, for, there being so much human and animal offal, more than the ordinary number of flies are bred. It was remarked during the Indian famine that neither beasts nor birds of prey looked healthy, and this was attributable to repeated surfeits of flesh, for one could scarcely go a mile through the country without meeting with half-devoured carcases. Many Indian officers had great experience in the conduct of famines, which was no easy matter. It seemed easy enough to establish a famine camp and to set the people to work on a road or tank, or at some other labour. But there was the sanitation and police of the famine camp, the provision for the sick, the convoy of food, the means by which it should be given to the people, the shelter of the masses, the care of the sick. Then there was the care of the numbers of sick, aged, infirm, and children, who were unable to leave their villages for any work. Various popular impressions had to be combated. One was that if a person could take food he did not die of starvation. During the Madras famine, Surgeon-General Cornish, C.I.E., who was then Sanitary Commissioner for the Madras Presidency, was obliged to point out this, and to insist that although a person took food yesterday, that was no reason why he did not die of starvation to-day; for there are two kinds of starvation—acute and chronic. Therefore the official relief of famine should not be delayed too long. Another delusion was that one pound of grain was sufficient to support a working man. This was also successfully combated by Surgeon-General Cornish. As a matter of fact, natives of India eat usually nearer 2lb. of grain per diem rather than 1lb., besides condiments. Another idea was that so long as the person got his allowance of grain it did not much matter what that grain was. But grains vary in nutritive properties, and feeding people who habitually take rice on bajree, or the reverse, is quite enough to produce bowel complaint. Most Anglo-Indians know if they change their horses' grain suddenly the horse will probably get "gripes." Sir W. Moore then mentioned the dietary which had been proposed by Brigade-Surgeon Lyon, the chemical analyst to the Government of Bombay. A question which arises is whether the people should be fed by doles of grain or should be given money to purchase grain. It had been found that when money was given prices had a tendency to rise; also that the money was not always spent in the most desirable manner. On the other hand, purchasers of large quantities of grain by the authorities disorganised trade, and grain could not be purchased so cheaply or conveyed so cheaply by the authorities as by the grain merchants. It was desirable that local conditions and circumstances should determine this. As regards prevention of famine, Sir W. Moore said that better cultivation and more of it was necessary. We could not, except to a certain problematical extent, control the elements, but at least we could store water. There were more than 18,000 miles of irrigation canals in India; but there were large tracts where there were no rivers for the extension of irrigation canals. These parts wanted more wells. And in hilly countries more storage and irrigation tanks were required. Forest conservancy was also a necessity, for by forest conservancy more rain would be solicited, and what fell would be prevented flowing away rather than soaking into the earth. More railways were also required. At present in India there were only some 18,000 miles of railway open. The problematical control of the elements mentioned above was rain making, of which we had heard much of late. If there were clouds, probably the compression produced by an explosion of dynamite might cause vapour to condense into water. But when there were no clouds, the moisture in the air would not be sufficient. There had no doubt been mistakes in dealing with famine in India; but such mistakes were nothing to those which apparently had been made in Russia. The authorities there did not seem able to carry out the orders of the Czar, and the grain had got into the hands of middlemen. It was also reported that Russian officials were generally corrupt. Now the Government of India had declared that if it were possible to prevent it no person should be allowed to die from want of food; and when famine was once recognised the local administrations and the local officials had nobly striven to carry out the orders of the Government of India. And as a rule they had succeeded, for the officials were English gentlemen, supplemented by Indian gentlemen whose one sole desire was to save the lives of the people. In this country during time of war safety from famine would depend on naval supremacy, for if the import of food were stopped, or materially interfered with, there would be much want, the agricultural resources not being sufficient for the large population.

In the discussion which ensued the President, Inspector-General Lawson, Surgeon-Major Hendley, Dr. Murray Thompson, and Dr. Bulstrode took part.

HUNTERIAN SOCIETY.

Ruptured Aortic Valve — Tuberculosis with Addison's Disease. — Recurrent Papillary Sarcoma. — Exfoliative Dermatitis. — Phosphorus Necrosis.

A MEETING was held on Wednesday, Dec. 9th, Dr. Stephen Mackenzie, President, in the chair (pathological evening).

Dr. F. CHARLEWOOD TURNER showed specimens from a case of Ulcerative Endocarditis.

Dr. F. J. SMITH showed a specimen of Ruptured Aortic Valve. A blacksmith aged fifty-two, of rather intemperate habits, complained of severe chest pain and dyspnœa, which had come on suddenly five days before. No syphilis or rheumatism. A loud double aortic bruit was heard. He died two days later. The heart was found of normal size; old atheroma affected the aorta and aortic valve, and one cusp of the valve was completely torn through.—The PRESIDENT referred to a case now under care, in which one chorda tendinæa is believed to be ruptured.

Dr. A. T. DAVIES showed specimens from a case of general Tuberculosis with symptoms of Addison's disease. A married woman, aged thirty-nine, had suffered from progressive weakness and pigmentation of the skin for three or four months prior to admission to hospital; also incontinence of urine for six years. The entire skin was coloured yellowish brown, being darker (of a dirty brown hue) in the axilla, neck, and pubes. There was slight exophthalmos and enlarged spleen. Temperature 99° to 102°; some pus in the urine, sp. gr. 1010. She died in ten days. The supra-renal bodies were found to be enlarged by tubercular growth, most of which had become fibroid; there were numerous giant-cells. The left kidney was reduced to a caseous mass; the right was hydronephrotic, with dilated ureter. The bladder was extremely contracted, with old

Digitized by Google

tubercular growth in the thick walls; it could not have held more than an ounce of urine. There were small patches of old tubercle in the lungs—fibrous at the right apex, caseous at the left. In Dr. Greenhow's classification of Addison's disease (Pathological Society's Transactions) the case would belong to the class in which general tuberculosis was present.

Dr. WIGHTWICK read notes of a case of Recurrent Papillary Sarcoma of the Toe, with numerous Secondary Growths. A man, aged twenty-eight, came under care in a dying condition, with growths scattered widely in the subcutaneous tissue and in the lymphatic glands and viscera. On the great toe was a small recurrent papillary growth five-eighths of an inch in diameter. Thirteen months previously several small, hard, warty growths had been removed from the toe, one of them slightly ulcerated. They were diagnosed as simple papillomata; the femoral glands, however, were slightly enlarged. The family history on the paternal side showed a marked tendency to malignant disease. His grandfather died at sixty of cancer of the cheek; one uncle and two aunts of some form of cancer.—Mr. JOHN POLAND, who had seen the case, described the post-mortem appearances, and exhibited microscopical sections of the recurrent and of the secondary deposits. The lymphatic glands in the groin, abdomen, neck, &c., the lungs, kidneys, supra-renals, liver, mesentery, and peritoneum were full of growth. There were numerous subcutaneous nodules on the trunk, other nodules in one of the papillary muscles of the right ventricle, in the mitral valve, and in the pectoral muscles. The reddish colour of portions of the growths was found to be due to small ecchymoses. The microscopical structure was almost precisely that found in melanotic sarcoma of the skin, without, however, any pigmentation, the cells being of the large round variety. But in the toe the cells were more mixed, many of them tailed. In some places the cells were closely packed, with little matrix discernible, giving an alveolar appearance. Ranvier describes this form of sarcoma of the skin.

The PRESIDENT showed a specimen of Exfoliative Dermatitis, a cuticular glove, presented to the London Hospital by Mr. Gooch in 1769. The patient, a gentleman aged fifty, had shed the skin of his hands and feet regularly twice a year for ten years. Before the exfoliation the parts were red and painful, with an eruption of red spots. The *American Journal of Medical Sciences* for last August reported a similar case; for thirty-three years the patient had shed his skin on July 24th in each year (!), the exfoliation lasting from five to ten days, with pyrexia &c. Scaly masses of cuticle from a case in the recent epidemic of dermatitis at the Paddington Infirmary were also shown.

Mr. CHARTERS J. SYMONDS showed a specimen of Phosphorus Necrosis of the Jaw, in which a large sequestrum had been removed, comprising nearly the whole of the lower maxilla, without waiting for it to become loose. The disease was arrested, new bone was formed, and mastication with the remaining two teeth was carried on.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

TUESDAY, DEC. 1ST, 1891.

Mr. ROBT. MERCER, M.R.C.S., President, in the chair.

Exhibits.—Dr. ARNOLD EVANS, medical officer of health, showed and described specimens of Fibrinous Bronchial Casts coughed up by a cow with pleuro-pneumonia, Kidney of Acute Nephritis ("black water") of Sheep, and Measly Pork showing Cysticercus Cellulosæ.

Spasmodic Torticollis treated by Neurectomy.—Mr. APPLEYARD showed a woman aged thirty-nine who had been treated for four months for spasmodic torticollis of gradually increasing severity. Drugs pushed to extreme limits had been unavailing, so the right spinal accessory nerve was cut down on in front of the sterno-mastoid and about three-quarters of an inch in length removed, the wound uniting directly, and the patient now being practically cured.—Dr. MAJOR advised surgical treatment in these severe cases, as medical treatment was without avail, and if left many of them tended to actual insanity.—Surgeon-Major COMYN, Mr. HORROCKS, and Dr. GOYDER also discussed the case.

Death-rates in Back-to-back Houses.—Dr. J. H. BELL read a paper, which will be published later, on this subject. He traversed the unanimous condemnation of all varieties of back-to-back houses by experts, stating that this condemnation was not supported by facts, and showed by extensive statistics extending over the past seven years, and drawn from nearly 2000 houses, that in certain classes of back-to-back houses over thirty years old, the death-rate was 15·8, in others, ten or twelve years old, it was 16·1, and in through houses, mostly ten to twenty-five years old, it was 17·3, the average death-rate of the borough in that time being 21·3.—Dr. ARNOLD EVANS, medical officer of health, criticised Dr. Bell's statistics as based on too few numbers to eliminate chance errors, and thought the comparison of old "through" with new back-to-back houses unjust. He was of opinion that back-to-backs as now built in Bradford were as healthy as that class of house could be made. He agreed with the body of opinion which condemned them.—Drs. GOYDER, DENBY, and the PRESIDENT continued the discussion.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

DEC. 17TH, 1891.

Mr. W. F. FAVELL, M.R.C.S., President, in the chair.

Dr. BURGESS showed a large Aneurysm of the Abdominal Aorta, and a Heart with a Perforation of the Mitral Valve and Vegetations on the Aortic Valves.

Mr. R. J. PYE SMITH exhibited Galezowski's Canaliculus Dilator.

Mr. SNELL introduced a patient who had had a foreign body (piece of steel) encapsuled in the lens for twenty-four years. The lens otherwise remained clear, and vision was still good.—Mr. R. J. PYE-SMITH made some remarks.

Dr. COCKING showed a case of Double Spasmodic Torticollis in a man aged forty-eight. For forty years he had been employed as a coal-getter ("timbering and holing"). There was no neurotic history. His health had been good up to twelve months ago, when he suffered from a spasmodic affection of the left arm, in which the elbow was slightly flexed, and the fingers suddenly extended, causing him to relax his grasp of the pick. This was followed by unilateral torticollis of the left side, complicated by a "shaking of the head" rather later, completely incapacitating him from work. When first seen, six weeks ago, there were rapid rhythmical oscillations of the head from side to side, the head being held stiffly in the middle line with a slight inclination forwards. The spasm came on in attacks, with short intermissions, and was occasionally replaced by unilateral torticollis. During the attacks both sterno-mastoids and the upper part of the trapezii were firmly contracted. There was also nystagmus on looking up and out, most marked on turning the eyes to the left. The bilateral spasm had recently considerably abated, and usually only a coarse tremor was then observed. When the patient assumed the position he generally occupied in "holing," the oscillations became extremely severe, and lasted for some time after resuming the erect posture. Nystagmus was still present. Dr. Cocking considered that the affection was due to excessive use of certain neck muscles required to maintain the head in the unnatural position necessitated by the patient's occupation. The occurrence of hammer—or pick—palsy with the torticollis bore out this conclusion. The association of both affections with nystagmus, which arose whilst working in candle-light, he regarded as corroborative of the view that "miners' nystagmus" was an occupation neurosis, called forth by overwork of certain ocular muscles which some kinds of work in coal mines required.—Mr. Court, Mr. Snell, Dr. Burgess, Dr. Dyson, and Mr. R. J. Pye-Smith took part in the discussion.

Polyuria and Retention.—Mr. B. WALKER related a curious case of Polyuria and Retention. A young woman aged seventeen was seized with severe abdominal pains. There was an impression that she might be pregnant. An examination disclosed retention of urine, and about eight pints were drawn off, the following morning seven pints, and again the next evening a large quantity, the urine being excessive for several days. A fortnight later she aborted, from which time she began to improve, and there was no further necessity for the introduction of the catheter.

Herpetic Fever.—Mr. COURT read a paper on Herpetic Fever, applying this term to a class of cases which he frequently met with, attended by an eruption of herpes labialis,

Digitized by Google

the eruption being accompanied by pyrexia, headache, vomiting and gastric disturbance, pain in the side, and frequently, but not invariably, by pneumonia. He proceeded to show that these cases ran a very definite course, the eruption appearing about the third or fourth day and lasting about six or seven days, the whole attack occupying from nine to twelve days. When pneumonia was present it differed from the ordinary type in not being marked by the usual stages, and in the small amount of expectoration in proportion to the extent of the lung mischief, recovery also being by lysis rather than crisis. In other cases the symptoms met with were chiefly abdominal. Mr. Court related the particulars of several of his cases as examples, some of them clearly showing the epidemic character of the complaint. He contended that the herpetic eruption had nothing in common with herpes zoster, but was rather the local expression of a constitutional malady caused by some specific poison like that of measles or scarlet fever. He further remarked on the favourable prognosis in cases of pneumonia which had herpes labialis for a trade-mark, quoting some observations of Dr. Hilton Fagge on this point, and arguing that this fact indicated a specific cause. Herpes did not occur in cases of pneumonia which arose secondarily to other morbid states, but only when the pneumonia was of a certain specific type. Herpes was not simply an indication of a febrile state, as it seldom if ever occurred in acute rheumatism, typhoid, or other specific fevers. On the other hand, an epidemic of simple herpes often coincided with the prevalence of epidemic pneumonia.—Dr. ST. CLAIR SYMONDS had found a new chromogenic micro-organism in the vesicles of herpes labialis, which he called the "bacillus viridans," and believed to be pathogenic.—Mr. COURT thought that this discovery might ultimately throw further light on the questions he had raised.—The President, Mr. B. Walker, Dr. S. Matthews, Dr. Dyson, Mr. James, Dr. Hargreaves, and Dr. Martin took part in the discussion.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

WEDNESDAY, DEC. 2ND, 1891.

Mr. A. R. ANDERSON, President, in the chair.

Occupation and Health.—Dr. WILLS, medical officer of health for Southwell, read a paper on occupation and health. He quoted statistics compiled by Drs. Richardson, Hirt, and Ogle to show the influence of various occupations on health, dwelling chiefly on those which were detrimental. He discussed noxious influences in regard to the etiology of tubercle, and exemplified such causes by means of death-rate tables. For persons predisposed to tubercle he recommended sheep-farming on the highlands of Cape Colony (altitude 2000-7000 feet), the climate of which he considered superior to that of Davos, Mentone, or the Canaries. The death-rates from phthisis in the army and navy respectively were in marked contrast, in the former case high, and in the latter singularly low—a difference which could only be attributed to the different character of the occupation followed by the members of each service. For persons who could not go away, he recommended out-door occupation in the country instead of living in the crowded streets and workshops of towns; and for women the culture of fruit and flowers was recommended as being light and remunerative employment. To provide for vicissitudes of weather, large glass-houses, similar to winter gardens, should be erected in situations as elevated and as near the sea as possible. In this case, work might go on all the year round. In this manner suitable hygienic conditions might be obtained for persons of small means, while the fatigues of travel, with its attendant risks of damp roads and bad drainage, would be avoided. The President, Messrs. Ransom, Tew, Powell, and Hunter took part in the discussion, and Dr. Wills replied.

Intussusception.—Mr. POWELL showed the intestine from an idiot, aged forty, in whom the chief symptoms were vomiting and rapidly fatal collapse, but pain seemed to be absent except in the later stages. There were two intussusceptions in the upper part of the jejunum, separated by healthy bowel.

Pyo-pneumothorax.—Dr. W. B. RANSOM showed the organs from a young married woman who died with symptoms of pneumothorax preceded by hectic of some duration. Post mortem there was found considerable matting between the stomach, liver, and parietes. Behind the stomach and liver was a large abscess cavity extending up to the diaphragm, through which pus and gas had made their way into the right pleural cavity. The patient had had hematemesis some years before; scars of old ulcers were found in the stomach, and it was supposed the abdominal abscess resulted from perforation of one of these ulcers, and that the resulting mischief had been localised by adhesions.

NEWCASTLE-ON-TYNE CLINICAL SOCIETY.

THURSDAY, NOV. 26TH, 1891.

WALTER RIDLEY, F.R.C.S., President, in the chair.

Cases.—Dr. J. A. JACKSON showed a case of Hodgkin's Disease with photographs. The patient was a boy aged eight. There was great enlargement of the left cervical gland, and the spleen was somewhat enlarged. There had been slight, but continued, fever for some weeks. The boy was anæmic, and examination of the blood showed the red corpuscles were only 76 per cent. The white corpuscles were normal in appearance and were not more numerous than in health. Drs. G. Murray, Oliver, Robertson, and Drummond made remarks.—Dr. SLATER showed a patient with Solid Œdema of the Leg. The condition appeared to be due to obstruction in the lymphatic vessels following an injury four years ago.—Dr. H. BAUMGARTNER and Dr. GEORGE MURRAY showed a patient who had been cured of an empyema by excision of ribs and drainage. There had been a large purulent effusion in the right pleural cavity. An incision had first been made in the sixth intercostal space and a drainage-tube inserted. As drainage did not take place properly, portions of the sixth and seventh ribs were excised. A few days later the cavity was washed out daily for a week with a warm solution of boracic acid. Ultimately the lung expanded well, the wound healed and a good result was obtained with but little deformity.—Drs. Smith, Mearns, Galloway, Percival, Oliver, Black, Lyon Smith, and Drummond made remarks.—Dr. W. ROBERTSON showed a patient with Pachyderma Laryngis Diffusa, in which there was thickening of the rima glottidis corresponding to that part of the mucous membrane covered by squamous epithelium. He also showed a case of Laryngeal Phthisis and two cases of Mastoid Disease.—Mr. BLACK showed a patient on whom he had performed Wheelhouse's operation, and had obtained a good result.

Mr. BLACK showed casts of an extreme case of Talipes Equino-varus, taken before and after the operation, in which the astragalus had been removed and the tissues in the sole of the foot divided. A very good result had been obtained. Dr. HUGHES showed the Larynx from a patient who had died of Diphtheria, which showed the false membrane still adherent.

Dr. Coley's interesting paper on the "Treatment of Coughs" was then read.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

FRIDAY, NOV. 20TH, 1891.

Dr. BRAITHWAITE in the chair.

DR. BRAITHWAITE showed (1) Cancerous Broad Ligament Cyst of large size; (2) Papilloma of the Hilus; (3) Apoplexy of the Ovary; (4) Microscopic Sections of Diseased Ovaries.

Mr. MAYO ROBSON showed (1) a large Solid Tumour of the Ovary (cystic sarcoma) successfully removed from a patient aged sixty-three; (2) a Large Fibro-cystic Tumour of the Uterus, removed by abdominal hysterectomy; (3) two cases of Tubal Gestation, removed by abdominal section. In both cases he found the abdomen full of blood; he first grasped the base of the tube with forceps, and then removed the clots and washed out the abdominal cavity with boiled water, removed the tubes and cyst, and put in a drainage-tube. Both patients recovered. Mr. Robson noticed in these cases that washing out the abdominal cavity seemed to restore the pulse, as it were, by a process of transfusion.

Dr. HELLIER showed the Appendages removed six weeks previously from a single woman of thirty. The diagnosis had been uterine myoma, with post-uterine tumour suspected to be ovarian. This was confirmed on section, an

Digitized by Google

ovarian cyst, the size of an orange, lying in the pouch of Douglas; right ovary also cystic. Result excellent up to date. He also showed a section from a case where the greatly enlarged uterus was lined by vegetating growth throughout. This was considered to be non-malignant.

Cancer of the Cervix Uteri.—Dr. J. F. HORNE (Barnsley) read a paper on the Necessity for Early Operation in Cancer of the Cervix Uterus. The patient came suffering from general debility, loss of flesh, with an irregular and profuse watery discharge from the vagina, which perhaps has lately become of a sanious, watery, and offensive character. Usually there is no pain; if present, it will be in the back, of a dull, gnawing character. When the growth has become parametric the pain is sharp, and often shoots down the thigh. Also the patient may complain of hæmorrhage following extra or painful menstruation or defecation. On vaginal examination we find the uterus possibly fixed, lips everted and enlarged, spreading like a mushroom in the vagina. In others the irregularly ulcerated surface of the cervix, soft and friable, with its hard and unyielding margins, are felt. The only treatment for these cases is amputation of the cervix as high up as possible. As illustrating this, Dr. Horne related the case of a woman aged twenty-nine from whom he removed the vaginal portion of the cervix for cancer. It was found that where the diseased mass had touched the vaginal walls deep ulceration of the mucous membrane had resulted. The surface was touched with a strong solution of chloride of zinc The patient made a good recovery, and a year after operation she looked healthy and well, and had gained weight. There was no vaginal discharge. The cervix was replaced by a puckered condition, which to the finger appeared quite healthy. The abraded vaginal mucous membrane appeared quite healthy.—Dr. BRAITHWAITE and Dr. HELLIER also spoke on this case.

Reid's Dilators.—Dr. BRAITHWAITE read a note on Reid's uterine dilators, relating several cases illustrating their good qualities. One was that of a lady aged thirty-four, unmarried, who had had dysmenorrhœa since she was eighteen. Had derived no benefit from the homœopathic physician who usually attended the family. Dr. Braithwaite dilated the cervix with Hegar's dilators to size 7, and inserted a large laminaria tent for the night. No benefit whatever followed this dilatation. A year after Dr. Braithwaite again dilated and used the tent as before, but on the second morning dilated with Reid's dilators to No. 4, not passing it quite up to the full length. The result has so far been an absolute success.—Mr. WRIGHT and Dr. HELLIER joined in the discussion.

Reviews and Notices of Books.

International Clinics: a Quarterly of Clinical Lectures by Professors and Lecturers in the leading Medical Colleges of the United States, Great Britain, and Canada. Edited by J. M. KEATING, M.D., J. P. CROZER GRIFFITH, M.D., J. MITCHELL BRUCE, M.D., and DAVID W. FINLAY, M.D. Vols. I. and II. Edinburgh and London: Young J. Pentland. 1891.

To those who remember the admirable clinical lectures of Trousseau and of Todd these two volumes may, at the first glance, be somewhat disappointing. They contain a great deal that is interesting, and yet the scholarly swing of forcible language which characterised the work of the great clinical teachers of a past generation appears to have almost died out. Still, the main idea is good, and in many cases the mode of treatment is satisfactory. Perhaps the first feeling of disappointment results from the difficulty of rapidly turning from one style to another, until all idea of personality is confused or lost. One great charm of clinical teaching surely lies in the recognition of the personal equation of the teacher. The cases described must of course furnish their own interest; but a good clinical teacher, whose previous work in any given direction is well known, can endow an apparently trivial case with valuable suggestive sidelights of information. On the other hand, a series of short lectures by a number of different teachers necessarily loses the personal element to a very large extent, especially when submitted to editorial suggestions, which probably tend to limit freedom of treatment. Each lecture indeed may in itself be satisfying, and yet the mental effort required to realise the new point of view assumed in each leads to a sense of weariness after the perusal of many pages. The volumes therefore are rather to be commended as books of reference than as guides which can be followed with sustained interest from cover to cover.

The leading idea is to make this periodical a complete post-graduate course of medical instruction, and as the "didactic professor" is said to present the position of the science of medicine in a formal and well-considered manner, the "clinical teacher" has to supplement the course of instruction by making the various formularies practical and applying them to the individual case. Notwithstanding this assumed distinction, it is consolatory to find the names of very many professors amongst the contributors.

With no less than thirty-six lectures in the first volume, and thirty-nine in the second, it is obviously impossible to criticise the work of the different writers in detail, still less to indicate how far their views are in accordance with those generally accepted. Even an enumeration of the subjects dealt with would reach to an indefinite length, as frequently one lecture will touch briefly upon some half-dozen or more cases in the wards; indeed, in one instance, no less than nine cases are described, illustrating totally unconnected types of disease. The surgeons are the chief offenders in this respect, several of the surgical clinics consisting of little more than the remarks made at the side of the operating table, with a line or two in brackets giving the subsequent history of the case.

In the first volume there is an interesting lecture by Dr. James Ross on acromegaly, this somewhat rare condition being well described, and the account being assisted by several plates. Dr. Porter lectures on polycæmia or plethora in its relation to inflammation. Mr. Christopher Heath, speaking of *dysphonia clericorum*, incidentally notes the rarity of this condition among elderly married clergyman. Dr. Gairdner discusses a case of hydrothorax with dexiocardia, and Dr. Mac Donnell gives a very complete history of a case of enlarged liver with jaundice, with his reasons for the diagnosis ultimately arrived at. Dr. Shattuck of Harvard deals with uræmic convulsions and with epilepsy, and then place is made for the surgeons. Professor W. Keen lectures on modern methods in surgical operations; Professor Cheever on ulcers; Mr. Hulke on a case of injury of the head; Professor Gaston on Wyeth's hip-joint amputation in a case of cystic sarcoma of the thigh; and Mr. Mayo Robson on cholelithiasis, noting in the course of the lecture the indications for surgical treatment. Gynæcology and obstetrics are dealt with by many teachers of well-established reputation.

Dr. Forchheimer gives an interesting account of tonsillar diphtheria, and Dr. L. C. Gray discourses on different types of paralysis in young children. Sir Dyce Duckworth lectures on chorea, and states that the future life history of some of the so-called non-rheumatic cases shows that rheumatic manifestation may supervene later. Professor H. C. Wood makes some interesting remarks on traumatic hysteria, regarding the treatment as largely a match between the character and wits of the physician and the character and wits of the patient. Lectures by Professor Ferrier on alcoholic paralysis and Professor Weir-Mitchell on the treatment of obstinate sciatic pain by splint rest and cold further enhance the value of the first volume.

The second volume is a worthy successor to the first, the chief papers in the medical section being those on ulcerative endocarditis, on the treatment of enteric fever by

Digitized by Google

systematic cold bathing, on the pathology of angina pectoris, and on lead colic. Catholicity of doctrine is illustrated in the surgical section by lectures respectively advocating gradual dilatation and rapid dilatation in stricture of the urethra; most of the other surgical lectures, however, refer to numerous unconnected cases. There are also several interesting lectures under the headings of neurology and of gynæcology and obstetrics.

Reviewing the contents of the two volumes, it may be safely asserted that this new quarterly venture will afford additional facilities for easily ascertaining the views of many of the clinical teachers of the day, and that it will thus prove a valuable addition to medical literature, even though it requires to be considered piecemeal rather than as a whole.

A Manual of Operative Surgery. By FREDERICK TREVES, F.R.C.S., Surgeon to and Lecturer on Anatomy at the London Hospital; Member of the Board of Examiners of the Royal College of Surgeons. With 422 Illustrations. London: Cassell and Co., Limited. 1891.

ONLY those who have attempted it are able fully to realise the difficulty of the task Mr. Treves set himself when he undertook to write a manual of operative surgery. The scope of such a work is very ill defined, and there are no rigid tests by which it can be limited. The literature of the subject is very extensive, the ways of accomplishing the same end are oftentimes very numerous, the small modifications introduced by individual surgeons are almost endless, and the force with which they appeal to others varies widely, while their true value often depends upon the peculiarities of a patient or even of the operator himself. What to choose from the mass of material is the writer's first great difficulty. To limit himself to those operations and methods with which he is himself familiar or which he prefers is to diminish the value of the book as one of reference very greatly. To include all methods and all varieties of operations is uselessly to encumber his pages. When this initial difficulty has been overcome there remains another quite as great in the manner of describing an operation. We have all read descriptions of operations which have formed no safe guide for their performance, and this not from their too great terseness or brevity, but from the writer's failure to place himself in the position of one quite unfamiliar with the details of what he has to do. The faculty of giving just the information required, of laying due stress upon the essential points without wearying with unnecessary details, is probably only fully acquired by those who for a long period have had to teach operative surgery.

Mr. Treves states in his preface that all his leisure for the past four years has been devoted to the preparation of this book. He has taken great pains to make himself acquainted with the literature of the subject—French, German, and English—and he states that his descriptions are founded upon personal experience in the operating theatre, and upon repeated operations upon the dead. He has made no attempt at "encyclopædic completeness," but has selected those measures that have appeared to him to be the best. Without endorsing it in every particular, we must say that Mr. Treves' selection appears to us to have been very judicious. This is a matter upon which entire unanimity cannot be hoped for, but we believe that candid readers and experienced operators will find very little to quarrel with in this respect in the book before us. The descriptions also are, on the whole, well done; in some cases they might certainly be more terse, but they will be found safe guides. The questions of the preparation of the patient for operation, the after treatment of the case, and the relative merits of different operations are sufficiently and aptly discussed. The anatomy of organs and regions is given with all necessary detail, and of course with accuracy. The indications for operation are not dealt with, and this is a matter on which many readers will wish Mr. Treves had taken a different view. There is much, no doubt, to be said in favour of excluding this subject from a manual dealing only with operative procedures, but for students and young surgeons such an addition would have been very acceptable. The majority of the illustrations are new and original, and they are admirable in design and execution—real helps to the reader. The feature of all others in this work which specially commends it, and in which it is in striking contrast to some manuals and text-books, is the pains Mr. Treves has taken to mention the work of other surgeons under their name. In very many instances operations are described in the very words used by those who first performed them, and the many modifications and details that are mentioned are carefully attributed to their authors. This is a special and a very praiseworthy feature of the book, and is the strongest evidence of the care taken in its preparation. The work is well up to date. We have met with one curious omission—there is no reference to operations upon varicose veins of the lower limbs.

The publishers have done their work well. The type is admirable, the paper good, and the edges cut, and the two handsome volumes are of a convenient size.

A Manual of Physics: being an Introduction to the Study of Physical Science. Designed for the use of University Students. By WILLIAM PEDDIE, D.Sc., F.R.S.E., Assistant to the Professor of Natural Philosophy in the University of Edinburgh. London: Baillière, Tindall, and Cox. 1892.

AS an elementary exposition of the application of mathematics to physics, Dr. William Peddie's manual is deserving of the highest praise. It should be extremely useful to students reading for honours at the universities, for it covers an extent of ground which is taken up by no other existing text book on applied mathematics that we know of, and Dr Peddie's treatment of both the mathematical and the physical aspects of the subject is extremely good, being thoroughly sound and scientific. The book reflects credit on the publishers, being well got up, clearly printed, and provided with excellent diagrams. At the same time, we are rather disappointed that Dr. Peddie has not seen his way to provide a text-book for another class of student whose knowledge of mathematics is limited. We are thinking especially of the medical student, for whom it is of the greatest importance to learn the fundamental principles of physics, that he may understand the instruments in constant use in the physiological laboratory and in the clinical ward, as well as the purely physical laws which govern the action of the body. Such a student, we feel sure, would find himself almost at once out of his depth on attempting to read this book. Dr. Peddie suggests that the mathematical portions may be skipped, but mathematics is everywhere so much to the fore that without it the book would be like Hamlet without Hamlet.

When Dr. Peddie finds a new edition called for, it might be worth his while to consider the wants of junior students. To this end the printing of the mathematical portions in smaller type might contribute. Certain subjects, such as the properties of matter, statics, and hydrostatics, might with advantage be treated at greater length. In this way, without diminishing the usefulness of the book for honours students, it might be made more serviceable to the wants of the great body of students.

OUR LIBRARY TABLE.

Text book of the Principles and Practice of Medicine. By the late CHARLES HILTON FAGGE, M.D., F.R.C.P., and PHILIP HENRY PYE-SMITH, M.D., F.R.S., F.R.C.P. Third

Digitized by Google

Edition. London: J. and A. Churchill. 1891.—The very thorough revision to which Dr. Pye-Smith has subjected this valuable work—perhaps the most important treatise on medicine that has ever been issued in this country—is more than sufficient to justify the use of his name as joint author rather than that of editor to Dr. Fagge's writing. It now includes whole chapters contributed by Dr. Pye-Smith on subjects which the original author did not live to complete, or which he had left only in fragmentary form, and, moreover, the rapid progress of knowledge in many directions of late years has necessitated the rewriting of many pages of the text and the introduction of much new matter. It would be tedious to specify in detail all these changes, commencing with the introductory chapter, which, in its terse and aphoristic style and rational views, is pleasant as well as profitable to peruse, down to the sections on Diseases of the Skin, which complete the work. It must suffice to say that nothing has been added that was not needed, nor anything excised that was not superfluous. Consequently the practitioner and the student have in this work as thorough and complete a survey of modern medicine and pathology as could well be desired. We may note, too, as not unimportant improvements which will greatly facilitate reference, the inclusion of the very carefully compiled index at the close of each volume and the recasting of the bibliographical index, which in its original form was of little use, but which now will be of great service. Lastly, Dr. Pye-Smith has introduced a new feature in scientific writings, one, perhaps, which has been left too much to writers of fiction. This consists in the placing at the head of each chapter some appropriate quotation, which stands as the motto for the subject dealt with. The selection of such quotations has been very happily carried out, and it gives a pleasing view of the wide erudition of the author who has availed himself of them. Nor are we so old-fashioned as to deprecate their introduction. Indeed, they afford a lesson in themselves, and show in matters of observation how the ages are linked together. "Fagge's Medicine" will, we may safely predict, long continue to be regarded as the most thorough and most scholarly treatise of modern times.

The Elements of Ophthalmic Therapeutics; being the Richard Middlemore Post-graduate Lectures delivered at the Birmingham and Midland Eye Hospital, 1889. By D. C. LLOYD-OWEN, Senior Surgeon to the Hospital. Birmingham: Cornish Brothers, 37, New-street. 1890. Pp. 68.—In these lectures Mr. Lloyd-Owen seeks to present to the general practitioner an epitome of the practical knowledge that has been acquired during the last few years of the action of drugs upon the eye. He gives a short but interesting introduction, stating that Mr. Middlemore, whose death at a very advanced age we had recently occasion to notice, had instituted a lectureship the first holder of which is Mr. Lloyd-Owen, whose lectures are contained in the work before us. The drugs to which he calls attention are atropine, cocaine, eserine, pilocarpine; the principal astringents, such as nitrate of silver, mercury perchloride, sulphate of zinc and of copper, zinc chloride, lead acetate, vinum opii, calomel, boric, salicylic, and carbolic acids; and, lastly, iodoform, resorcin, hydroquinone, and iodol. He does not mention the allied compound salol, which has been found useful as an antiseptic. He discusses the relative value of the application of heat and cold and of bloodletting. In regard to internal remedies, he has found small doses of the bromide of potassium and chloral, repeated at regular intervals, to be very effective in calming the irritation which so often accompanies phlyctenular keratitis in children. A final chapter is devoted to internal remedies, and especially to the effect of narcotics and quinine. These lectures will put the practitioner *en rapport* with all recent work in this direction.

An Atlas of Illustrations of Pathology. Fasciculus VIII.: Diseases of Brain and Spinal Cord. The New Sydenham Society. London: H. K. Lewis. 1891.—The New Sydenham Society is doing good service in issuing a series of pathological drawings which are extremely well executed and faithful. The present instalment of the Atlas contains plates in illustration of hydatid disease and abscess of the brain, as well as of tubercular tumours, besides several of lesions of the spinal cord. Most of the plates in this fasciculus are reproduced from Auvert's Atlas, which is but little known in this country; but two showing the effects of compression of the cord from fracture of the spine are from Mr. Hutchinson's collection. The explanatory text is clear and concise; and indeed the whole production is highly creditable to the Society, and will be much appreciated by its members.

Elementary Inorganic Chemistry, Theoretical and Practical. By A. HUMBOLDT SEXTON, F.R.S.E., F.I.C., F.C.S. New Edition. London: Blackie and Son, Limited, Old Bailey, E.C. 1891.—Of this little work, as of scores of other similar works, we can only say that, while no exception can be taken to the matter contained therein, it possesses no special element of novelty. It is an extension of the author's lectures delivered to students at evening classes, and is really intended for those who present themselves for the examination in Chemistry held by the Science and Art Department. The author has, indeed, thought it advisable to keep the requirements of the syllabus before him in preparing the book, although he has not hesitated, he confesses, to go beyond the syllabus where it has seemed good so to do. Had he included an account of such elements as bromine, iodine, fluorine, and devoted more than nine pages to organic chemistry, the book would have been more useful. As a practical introduction to the science, however, for the use of those students already referred to it is well fitted to serve.

The Asclepiad. No. 32. Vol. VIII. By BENJAMIN WARD RICHARDSON, M.D., F.R.S. London: Longmans, Green, and Co.—This number concludes the eighth volume of what is certainly one of the literary marvels of the day—a quarterly journal full of original thought and the record of personal investigation, which from end to end is the product of a single pen. The felicity of its author's style and the wise selection of topics combine to render it one of the most readable of serials, and sufficiently account for the measure of success which his bold venture has attained. One noteworthy feature of the *Asclepiad* consists in the faithful biographies of departed medical worthies which run through its volumes. The memoir this time is of a man whose life and work are, we fancy, known to but a few of the present day. Yet his was a notable figure, and he left his mark upon medicine and literature, more perhaps in the latter than the former department, for he was the author of works of fiction and history, including a sketch of the French Revolution, of which he was an eye-witness. This was Dr. John Moore, whose fame, perhaps, as Dr. Richardson suggests, has been eclipsed by that of his soldier son, the hero of Corunna. The autotype reproduction of Dr. Moore's portrait which accompanies the memoir shows us a face of strongly marked intellectual type and benevolent aspect. It is impossible to see it without understanding the esteem in which he was held by his contemporaries. Dr. Richardson gives us a fourth and concluding part of his monograph on Peroxide of Hydrogen, containing several formulæ for the exhibition of this powerful agent. A characteristic and charming essay on the Physiology of Tears follows. Then there are several "Opuscula Practica," which comprise such matters as cranial auscultation, the diagnosis of arterial cranial murmur, and labyrinthine disease, saline transfusion, &c. In a lecture on the "Cerebro-spinal Axis as a Thermal Centre and Water-power," the author introduces a new theory

Digitized by Google

of the *modus operandi* of the nervous system, in which the cerebro-spinal fluid takes a prominent share. The number concludes with reviews and book notices, which we are glad to learn are to be given more space in the future.

Analytical Records.

PALATINOIDS AND BI-PALATINOIDS.

(MESSRS. OPPENHEIMER, SON, & CO., 14, WORSHIP-STREET, E.C.)

IT is now somewhat more than a year ago that we gave prominence to a new and elegant method for the administration of nauseous and unstable drugs. At that time we published a full account of the examination and analyses made, and the results were so good and satisfactory as to be assigned no small section of the space usually allotted to THE LANCET Analytical Records. A palatinoid consists, as it was then explained, of a thin air-tight jujube, containing the medicament in a pure and finely powdered state. By its employment an excipient is thus dispensed with, the taste of nauseous drugs like the valerianates and quinine effectually disguised, and the unpleasant effect of iron salts, for example, in the mouth and on the teeth obviated. The shape of the palatinoid is conveniently bi-convex, and it is composed of jujube material, which, when moistened by the saliva, becomes slippery, enabling the patient to swallow it without any difficulty. According to our previous experiments, the contents are discharged in about three minutes after immersion in water at 100° F. While we recognise in the palatinoid one of the best methods for the administration of unstable and nauseous drugs that have hitherto been devised, yet we think that the bi-palatinoid recently introduced by Messrs. Oppenheimer and Co. is entitled perhaps to even greater praise by reason of the ingenuity and skill which it displays. The ordinary palatinoid has probably given rise to the idea of the double or bi-palatinoid. The former is intended to administer inert or compatible ingredients, and the latter incompatible ingredients or ingredients that readily decompose one another, resulting in the production of a newly desired compound. Practitioners have long recognised the difficulty of administering many of the valuable combinations of the proto-iron salts in a satisfactory and pure condition. Griffith's Mixture (Mist. Ferri Co. B.P.) and Blaud's pill, for example, are so made as to give, as a product of double decomposition, pure ferrous carbonate. Both, and especially the former, undergo more or less rapid change by oxidation into persalts. A mixture of solid potassium carbonate and ferrous sulphate, as in Blaud's pill, even if only slightly moist, gradually decomposes and forms oxy-salts. Still more unsatisfactory are the B.P. preparations of ferrous arseniate and phosphate. The Pharmacopœia allows, it would appear, no less than 55 per cent. of impurity in ferrous phosphate, and 90 per cent. in ferrous arseniate. Any method therefore which aims at securing greater ease of administration, greater accuracy of dosage, and accordingly a full and more certain therapeutic effect from medicaments such as those mentioned, will, as a matter of course, meet with hearty and very general approval. If clinical experience is found to confirm the excellent results obtained with Messrs. Oppenheimer's bi-palatinoids in the following chemical analyses, then their employment places the administration of exceedingly unstable compounds, like ferrous carbonate, phosphate, and arseniate, upon a sounder and more scientific basis. The bi-palatinoid resembles the ordinary palatinoid as regards appearance and shape, but it contains, in addition, a septum of thin pure jujube, which serves to separate incompatible ingredients. In the event of the presence of a third or

fourth ingredient it is placed with the compatible substance. In the bi-palatinoids examined, for example, phosphate of soda, nux vomica, and aloes were present in the compartment containing the carbonate of soda, the iron salt in all cases being apart. The bi-palatinoids enumerated below averaged in diameter about a quarter of an inch and in depth one-eighth of an inch. Like the ordinary palatinoid, they soon open under the solvent influence of lukewarm water and discharge their contents, which at once react to produce a new compound in a perfectly fresh, moist, and pure condition, and not improbably in that active state chemically known as nascent. The experiments conducted in our laboratory not only show that this action does take place, but they also indicate the especial precaution that has been taken to ensure the exact proportion of ingredients which are to react to produce the proper quantity of the new medicament. For the purposes of experiment the palatinoids were dissolved in oxygen-free water, resting under a layer of light petroleum, so as to exclude air. The resulting precipitate was allowed to subside and the excess of water removed, and the precipitate washed with oxygen-free water several times by decantation. It was then analysed and examined. The ingredients of each bi-palatinoid were also carefully separated and analysed. There is no need to offer any interpretation of the results—they are so palpably satisfactory.

CITY OF LONDON SANITARY SLATE.

(J. BEEDZLER & CO., NORTON FOLGATE, WORSHIP-STREET, E.C.)

According to the highly characteristic smell and to the physical constants we were able to obtain, the substance of this slate consists of practically pure naphthalene, a hydrocarbon which is in some instances a valuable disinfectant and antiseptic. Naphthalene melts at 79° C., and boils at 218° C. The figures actually yielded by the above preparation were—melting-point, 79·5° C.; and boiling-point, 217° C. We were not able to satisfy ourselves that carbolic acid was present, as, on shaking some of the powdered material with caustic soda solution and filtering, no precipitate was obtained on adding acid and bromine water to the filtrate. The sanitary slate may possess certain value as an antiseptic &c., but it can hardly be claimed to act as an aerial disinfector of any power. A more probable advantage, we imagine, would be gained from its employment as a preventive against the attacks of midges, mosquitoes, and similar pests. The slate is made in a form convenient for hanging upon the walls of a room or closet.

ESENCIA DE CALISAYA.

(MOSQUERA JULIA FOOD COMPANY, DETROIT, MICHIGAN, AND NEW YORK.)

This preparation is described as a tonic of great merit in all cases where the use of cinchona is indicated. It has the colour and appearance of port wine, is slightly acid in reaction, and somewhat syrupy in consistence. It is sweet and pungent to the taste, and produces a warm sensation in the throat much in the same way as a liqueur, but leaving a distinctly bitter flavour in the mouth. The active principles of Calisaya bark were successfully extracted. Inasmuch as each ounce is said to contain the equivalent of four ounces of bark, it is no doubt a valuable as it is an elegant preparation.

BENZOZOL, OR BENZOYL GUAIACOL.

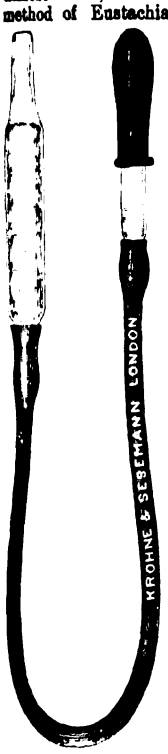
(BURROUGHS, WELLCOME, & CO., SNOW HILL, E.C.)

Benzoyl guaiacol, according to Jacobsen, occurs in the volatile oils that are invariably associated in small quantity with the benzoic acid obtained by subliming gum benzoin. It is a white crystalline substance, and is said to be decomposed in the digestive tract into its proximate constituents, benzoic acid and guaiacol. Within half an hour after ingestion the latter body can be detected, it is stated, in the saliva and the urine. Guaiacol, it will be remembered, is a diatomic phenol, and is represented by the formula $C_6H_4OHOCH_3$. Though not soluble in cold water, benzoyl guaiacol appears to undergo gradual decomposition in hot water. Our own experiments showed that this interesting substance melts under boiling water, melts and then burns with sooty flame when heated on platinum foil, and dissolves readily in alcohol. It dissolves also in cold sulphuric acid, and on pouring the solution into water benzoic acid separates, and may be collected and tested. Benzozol is described as useful in cases of incipient phthisis, and as an agreeable and harmless substitute for creasote.

New Inventions.

HICKS'S NEW PATENT CLINICAL THERMOMETER.

WE have received some specimens of clinical thermometers devised by Mr. Hicks, which are accompanied by testimony from Mr. Whipple, the superintendent of Kew Observatory, showing, as the result of his experiments, that these instruments record the temperature of the blood in periods of from half a minute to a minute and a half. This desirable object has been attained by reducing the bulk of the bulb, and also dispensing with the usual contraction in the stem which is to be found in all other clinical thermometers at a distance of about one inch from the bulb. In that pattern, therefore, the graduation of the thermometer commences at some distance from the bulb, adding to the length of the instrument. Moreover, in the contraction there was a small chamber which retained a quantity of mercury equal to about ten or twelve degrees of temperature. This quantity of mercury was so far away from the bulb that it seldom got properly heated, as it was quite beyond the reach of the mouth, causing the thermometer to be sluggish in registering a true temperature, and the contraction was a point at which the thermometer usually broke when dropped. The "Non Plus Ultra" has no contraction in the stem, and no chamber to contain superfluous mercury. Its constriction is made in the top of the bulb itself; consequently, the whole of the mercury gets thoroughly warmed at once, and the temperature is not only recorded more accurately than before, but in half the time. There being no contraction in the stem, the space of one inch (referred to above) which used to be wasted is now turned to good account, as the divisions and figures are brought down close to the bulb. The scale of the thermometer is therefore rendered nearly twice as open as before, and is much more easily and accurately read. The indestructible index is, of course, retained. A four-inch "Non Plus Ultra" clinical thermometer will show as open a scale of graduations as that previously provided on a six-inch thermometer. The maker claims for the "Non Plus Ultra" greater accuracy, greater strength, and quicker action. Notwithstanding these advantages, there is no increase in the price. We may add that we have found this thermometer to possess the advantages claimed for it, and can recommend it to the profession.



AN EUSTACHIAN INFLATOR FOR SELF-USE.

I HAVE long made use of the act of blowing on the part of the patient as an easy means of opening the Eustachian tube during the operation of inflation of the middle ear by the Politzer bag, and Dr. Ward Cousins employs the same

Digitized by Google

principle in the use of his tympanic evacuator and inflator. At the same time, it must be admitted that for adults the swallowing of a little water is superior to mere labial blowing; but in the case of children the preferability of the blowing method is unquestionable. What I consider is almost worthy of being termed "a simplified and improved method of Eustachian inflation for children" consists in gently blowing up the nostril by means of Politzer's bag while the child blows through a tube with a very narrow bore, such as an Eustachian catheter or a pipe-stem, at the same time puffing out the cheeks.

On the same principle I have provided a number of my patients with what I call the "Eustachian Self-Inflator." It consists of the not very novel structure of a piece of india-rubber tube about $\frac{5}{16}$ in. in internal diameter and of about 12 in. in length. At one end is a glass tube, covered with an indiarubber teat, and adapted to fit comfortably into the nostril. At the other end is a glass mouthpiece, with a bulbous swelling, into which is loosely packed a little cotton-wool (*vide* engraving). On to this wool I drop a few minims of chloroform, and instruct the patient to blow two or three times through the tube while sniffing cautiously at the other end till the extreme pungency of the chloroform passes off. He then inserts the nosepiece into one nostril, closes the other, and blows. It is well known that air or steam enters much more easily into the Eustachian tubes if mildly impregnated with chloroform vapour, and I have taken advantage of that fact in devising the self-inflator. If an ordinary breath is insufficient to inflate the tympana, additional power may be obtained by the patient previously drawing a full breath. At the same time, I urge the patient to exercise the very smallest amount of pressure, which is sufficient to make the vapour "go to the ears." Should it be desired to limit the inflation as far as possible to one ear, the head is to be held to one side with that ear upwards, while the other is plugged with a finger of the patient or of someone at hand.

In several cases of most obstinate middle-ear catarrh, even where Politzerisation and the use of the catheter produced little or no improvement, this method has afforded a remarkable and most unexpected amount of benefit as regards hearing power, subjective noises, and fulness in the head. The instrument is made by Messrs. Krohne and Sesemann, Upper Wimpole-street, W.

DUNDAS GRANT, M.A., M.D., F.R.C.S. Eng.

CASUALTIES DUE TO FOG AND FROST.

THE following is a list of the cases, due chiefly to the effects of the recent fog and frost, which have either been admitted to metropolitan hospitals during the past week or treated in the out-patient departments.

London Hospital.

During the week which ended with Saturday last the following cases were treated. The cause of the accidents &c. is not noted in the receiving-room, but the officers on duty state that very large numbers resulted from the slippery state of the streets, as may be gathered from the following returns of the cases. The accident cases received into the wards or made out-patients consisted of 51 fractures, 6 dislocations, 24 sprains, 4 concussions, 13 contusions, 50 lacerated scalp wounds, and 1 rupture of the globe of the eye. The minor casualties treated, but not made out-patients, consisted of: Sprains or contusions of the shoulder, 23; of the elbow, 13; of the wrist, 23; of the fingers, 12; of the hip, 9; of the knee, 10; of the ankle, 24; of the toes, 6 of the back, 18; of the side, 23; of the jaw, 2; 8 lacerations of the finger, 4 of the face, 8 of the scalp, 5 of the forehead. In twenty-four hours—Dec. 25th and 26th—11 cases were seen of fractured radius either with or without fracture of ulna.

Westminster Hospital.

As the result of the fog and frost, the following cases of accident or illness have been received at this hospital. Admitted to the wards: Fractured femur, 2; fractured fibula, 1; fractured tibia, 1; injury to elbow, 1; injury to ankle and knee, 1; injury to head, 2. In addition, there were fully 25 surgical casualties on December 25th attributable to the frozen condition of the streets. In the medical department 8 patients are at present in the wards suffering from bronchitis brought on by the fog; and, in addition to these, 9 patients died between Dec. 22 and Dec. 27, of whom the deaths of 6 were either directly due to or accelerated by the state of the atmosphere.

The Royal Free Hospital.

The cases of accident or illness treated in the Royal Free Hospital as a result of the recent severe fogs and frost were very numerous indeed, the books of the institution showing a total of some sixty or seventy. The greater number were received between Christmas-eve and the early hours of Christmas Day, on which occasion two of the resident staff were up all night owing to the very serious nature of some of the cases. Three or four patients had to be admitted into the wards, the most serious being a man run over on the railway, whose leg had to be amputated, and a woman who fell in the street and injured her head. Among the number who were able to leave after treatment were four dislocations, six fractures of arm, and four fractures of leg, including the case of a cripple with a contracted leg.

St. George's Hospital.

From this hospital we learn that 17 cases of accident and illness due to the fog and frost were admitted as patients.

The Middlesex Hospital.

During the week ending Saturday, Dec. 26th, the surgical cases admitted into the hospital as in-patients whose injuries could in any way be traced to fog and frost were as follows: Scalp wounds, 4; fracture (jaw), 1; fracture (?skull), 1; fibula, 2; tibia and fibula, 2; and one man was brought in dead from apparently fractured base. This was the only death directly due to the causes mentioned. From Dec. 21st to Wednesday last 30 cases were admitted into the medical wards. These have included pneumonia 3, acute nephritis 2, bronchitis 12, 3 with heart disease (of whom two died), asthma 1. The bronchitic cases may certainly be attributed to fog, as also the deaths in heart disease with bronchitis. During the corresponding period there have been 13 deaths, about treble the usual number.

St. Mary's Hospital.

The fogs and frost of the last week were responsible for the admission into this hospital of twenty accident and five medical cases. Most of the accidents were on Christmas Day.

St. Thomas's Hospital.

The account we have received from this hospital does not give particulars of increased accidents during the recent exceptional weather. About twenty cases were treated in the surgery for accidents which occurred during the fog.

FOOTBALL CASUALTIES.—Whilst playing in a match on the 19th ult., between Blackpool South Shore and West Manchester, at Blackpool, a player fractured his leg below the knee. On the same day a young man, aged nineteen, playing in a match (the St. John's Club against the St. Paul's) at Bedminster Park, sustained a compound fracture of the elbow, and was removed to the hospital.

FOULING THE THAMES.—George and Robert Morgan and William Haimer were summoned at Staines Petty Sessions this week by the Thames Conservancy, for having emptied the contents of a cesspool into the Thames, just above the intakes of the Metropolitan Water Companies. The case was proved by a Conservancy official, and defendants were fined 50s. each.

THE LANCET.

LONDON: SATURDAY, JANUARY 2, 1892.

WITH the publication of the present number, THE LANCET enters upon its seventieth year. The coming and going of the years has been from time immemorial the occasion, to minds disposed to meditation, of pensive and salutary thoughts; indeed few, and not greatly to be envied, are those persons whose buoyant spirits carry them, without a pause for reflection, hurrying past the milestones of life. To most of us the closing of our annual volumes and the start upon a new year suggest superabundant matter for thought, and thought not untinged with sadness. Quite apart, however, from any question of the pleasantness or pain of indulgence in such reflections, there is a very definite gain to be secured—at least, in the case of those who are coöperating towards a common end—by pausing periodically to report progress, and revise the programme upon which the joint adventure is being worked out. It is in the spirit of this idea that we have been accustomed at the beginning of the year to take our readers into our confidence and to recapitulate for their information, not only events of a scientific and public character such as form the material for our *Annus Medicus* review, but also those matters of comparatively private interest which relate to the work and position of THE LANCET in the world. Indeed, the successive Editors, who have always been members of the family of its founder, the late Mr. WAKLEY, have ever cultivated the feeling that readers of THE LANCET are not only their supporters and subscribers, but also coöperators with them in the task of representing and recording the mind of the profession at large. The steady support of medical practitioners throughout the British Islands, and, indeed, throughout and even beyond the English-speaking world, has enabled them to establish and maintain an independent organ of professional opinion and intelligence, which is conducted in the interests of no party and no school, but contains so far as may be an exposition of all shades of opinion, and a record of all varieties of professional and scientific work. This ambitious object can only be in any measure attained by the willing coöperation of our professional brethren both at home and abroad; and it is the abundance of the aid thus rendered which makes us feel that some more or less confidential communication with our readers on the subject of our work is at this season in no way out of place.

It is, then, with the liveliest satisfaction that we realise that the representative character of THE LANCET has never been so well sustained as at the present moment. The gradual, in recent years the rapid, growth of the weekly number is of itself a testimony to the extent to which our pages are made the channel of intercommunication between the members of the medical profession. In the year 1887 the normal size of THE LANCET was ninety-six pages, although during that year it exceeded this bulk on all but two occasions; indeed, it once attained to 144 pages. Since that date it has received repeated enlargements, and during 1891 its normal bulk has been 112 pages, a size which will in 1892 be further increased to 120. The additional accommodation thus provided is, however, by no means a full, or, indeed, any adequate measure of the extent to which demands have been made upon our space. On no occasion during the past year has THE LANCET contained only 112 pages. Its average size, to be precise, has been 137 pages; on two occasions the numbers extended to 200 pages, and the present issue also contains 200 pages.

In another direction also the development of this intimate relation with the medical profession has been equally marked, for the manager reports that during 1891 his sales exceeded by upwards of 48,000 copies the corresponding figures of any previous year. These very remarkable facts show in a manner, which is highly gratifying to those who are charged with the conduct of the journal, that they have not laboured in vain to secure the confidence and good opinion of their professional brethren.

It is, perhaps, hardly necessary at such a time as the present to say that the Editors of THE LANCET are not engaged in private practice, and that it is with them an inflexible rule that no private interest is suffered to come into competition with their public duty as medical journalists. They have engaged in no speculations and attached themselves to no interests which could have the effect of shaping their course or affecting their policy in the conduct of THE LANCET; and they would regard any proceeding of that sort not only as the height of imprudence, as tending in some greater or less measure to fetter their independence and so imperil their position, but also as a serious breach of the duty which they owe to their supporters, whose confidence would certainly and justly be withdrawn if it were supposed that private motives were allowed, whether consciously or unconsciously, to influence the utterances of THE LANCET.

Passing now to our work in its various departments, we may allude, in the first place, to the large and most useful expansion which has taken place in recent times in our correspondence columns. As far as our readers are concerned, it is not easy for them to transgress the very wide limits of available subject matter, for nothing whatever of professional interest comes amiss in these pages. The result is too familiar to those whom we now address to stand in need of any description. Our correspondence columns contain not only the most comprehensive treatment of medical questions, whether scientific or ethical, but also a very large number of communications of the highest originality and importance. During the past year some 2090 pages have been devoted to this section of the journal, and it will, we think, be generally admitted that they have worthily exhibited the drift and movement of medical opinion.

Of the lectures, original and special articles, reports of societies, mirror of hospital practice, and editorial comments upon current topics, which have formed the staple of our literary matter from week to week, it is not necessary here to speak at any length, because that has been incidentally touched upon in the *Annus Medicus* article already referred to, since in some one or other of these

Digitized by Google

departments every one of the topics is brought before our readers which eventually make up the public record of the year's medical work. But any summary of the present kind would be incomplete which did not glance at the Special Supplements which we have from time to time produced in support of objects of special interest from a medical point of view. Foremost among these is the Hospital Sunday Supplement, which in 1891 was distributed in large numbers throughout the places of worship of the metropolis—some 100,000 copies were circulated in this way,—but 40,000 additional copies were also, at our suggestion, privately circulated by the medical practitioners of London among their wealthy and charitably disposed patients. The direct and visible result of this appeal was most gratifying, and contributed in no small degree to the marked success of the collection, a success that was attained under conditions distinctly unpromising, and such, indeed, as occasioned no little foreboding of failure until the actual result was made known. Of this we are able to speak with the greater freedom, because the result, which we are able to record with such unfeigned satisfaction, was distinctly due not to our skill or energy as medical journalists, but to the generous response made by our readers to the suggestion that they should personally interest themselves in promoting the success of the collection. They possess, as has been previously said, a special right to speak on such a subject and to urge the claims of charities which they support not only with money, but also with their services. It was not likely that their authority would be questioned if they chose to speak on such a theme. We knew, and the public also now knows, that the medical men of the metropolis are prepared to support with their good word the medical charities with which they are associated, both within the routine of professional service and without that routine. This is as it should be, and it is gratifying to be able to add that when thus approached the public will be found prepared to respond in a generous manner, and to extend an ungrudging support to institutions whose claims are avouched not only by well-disposed patrons, but also by competent critics. This is a consideration which will not be lost sight of, either by our readers or ourselves, when the occasion for a new Supplement comes round.

Nor must we pass wholly without remark the Special Supplement which was issued in November last dealing with life assurance and the medical profession. That this is a subject which merits more attention than it has heretofore received is made evident both by the facts which are constantly coming to our knowledge in connexion with the administration of THE LANCET Relief Fund and also by the concessions and advantages which it has proved possible to secure for medical men by the simple process of asking for them. It will, we hope, prove in the end that medical men have gained, not only in increased facilities for life assurance, but also in an awakened sense of its importance and advantage through the ventilation of the topic in our columns.

This survey of the past year leads naturally to the reflection that the year upon which we have just entered will make its own demands upon us all, writers and readers alike, and that to meet and satisfy those demands will require a continuance of the coöperation which has brought about in the past the results here recorded. Speaking for ourselves, we shall spare no effort to rise to the occasion as it presents itself, and we shall look with assured confidence to our subscribers to renew their support. The objects which we have in common are not personal, nor are they merely professional. They touch the largest and most abiding interests of our neighbours as well as of ourselves, and in working for success in the task to which we have set our hands we are also working for the common good. In this connexion we would allude to that excellent institution the Epsom Medical Benevolent College, and must express our regret that its treasurer, Dr. HOLMAN, has not so far been as well supported as he deserves to be in his plea for the pensioners. We would again direct the attention of our readers to the claims of this excellent medical charity, and may add how pleased we shall be, when the conditions are fulfilled, to be called upon to pay our promised £1000.

We must also mention the International Congress of Hygiene recently held in London, when with an army of reporting experts we were enabled to publish the fullest and most scientific report which appeared of the proceedings of that historical meeting, extending as it did to nearly 200 pages of THE LANCET, and consisting of highly technical and important matter. We also republished in pamphlet form all the reports which had appeared in THE LANCET of previous meetings of these Congresses, copies of which, to the number of 2000, were presented to those members who took part in the Congress.

THE devotees of medicine have this great satisfaction, that the science which they pursue is a progressive one. It does not profess to be based on revelation, like theology, and it is not fixed and settled in its principles as is the law. Medicine is not only progressive, but it progresses by leaps and bounds. To men not yet very old the changes in the fundamental conceptions of medicine seem enormous, and there is no reason to think that we are at all near reaching finality. In a very lucid and instructive graduation address on the service rendered to mankind by medical science, Professor RUTHERFORD remarks how late has been her advance. For centuries she was a slave to names. GALEN was her god. But such physiological discoveries as HARVEY'S and such chemical work as PRIESTLEY'S broke the charm of mere authority, and taught men to look to nature herself and to investigate her secrets. And the result has been that in the last 120 years, and especially in this century, the progress has been enormous. We endeavoured in our summary of last week to show what had been done in the short twelve months, and it may safely be said that the record of work involved an amount of saving of life, of limbs, and of pain which would be incapable of being understood by anyone who had twenty-five years since abruptly ceased to study medicine. The encouraging thought at the opening of another yea is that there seem to be far greater gains in prospect for the earnest student of medicine than even those which have yet been realised. Whole regions of disease invite investigation, and promise to succumb before the defined and determined attacks of recent science. We are all the wiser this year for the great disappointment of last. It has taught us perhaps

Digitized by Google

to be slower in our conclusions, but it has not in any degree lowered the prospect of ultimate success. The impression already made on large bodies and classes of men in regard to the risks and incidence of phthisis and the increasing number of reports of recovery in individual cases are enough of themselves to make us hope that tuberculosis itself will be brought more under the control of medicine, and the insanitary conditions which lead up to it and make it possible will be gradually reduced under wise and beneficent legislation. This is still the greatest problem before physicians, as the disease to be mastered is the most disastrous to the sufferer and the most discreditable to the profession. Like that of the specific infective diseases, it will require the coöperation of various scientific workers for its elucidation. And this is the happy case of Medicine, that she is served by chemists and physicists and biologists of every kind, and that all are eager to do for large groups of diseases what has already been done so brilliantly for others. The somewhat discouraging note that has been struck of late by one or two physicians in reference to the arrest or non-curability of phthisis has not been responded to by the profession, and is not likely to be. Professor FINLAY has just published a case of recovery from tubercular peritonitis and double pleurisy, read to the Clinical Society, and properly makes much of the more hopeful tone, as respects tubercular peritonitis, of physicians in recent days as compared with that of physicians of a former generation.

As we have suggested, the hope of progress in regard to the nature and properties of the specific infections in the near future rests much on the work of men of research in the regions of chemistry and biology. It is to be lamented that there has been so much in our law that has hindered the natural tendency of Englishmen to come to the front in these investigations. But, as Professor BURDON SANDERSON lately said, there are signs of improvement. The laboratory of the combined London Colleges is a living proof that they mean to encourage such researches. They could not make a higher use of their resources. And the pressure and dread of unpleasant forms of disease will, we must hope, gradually induce the Government and the Legislature to relax those so-called antivivisection laws which are discreditable to the intelligence of the British public. Small-pox—the *bête noire* of the English public—happens to be in abeyance just now, and this fact is making them faddish in regard to the value of the one great fact and discovery of British preventive medicine. But there is another disease that is showing increased virulence that may well frighten the public into its senses and induce it to give a free hand to those who are prepared at all personal risks to investigate it. We refer, of course, to diphtheria. Twenty years ago this disease was scarcely ever seen in some parts of London and in other large towns. Now it is a veritable scare. It must be confessed that our knowledge of its origin, its nature, its relation to other infections and other diseases of man and animals, and of its mode of propagation, is very vague. Many members of the profession, most of them brilliant and promising, have fallen victims to their duty in connexion with

Many more are prepared to take all risks. If the Legislature will do its duty, the profession will soon throw more light on this difficult question. We have said that much depends with regard to medical progress on the research section of our profession. But much, too, still depends on those in general practice. Take this very disease of diphtheria. Who but general practitioners can give an account of first cases, of their relation to other diseases in man or animals, and of their behaviour under treatment? We confidently hope that the year 1892 will be a satisfactory one to all classes of practitioners, and that some of the more obscure and intricate problems of disease will receive elucidation, if not solution, ere it too, in its turn, is numbered in the ranks of the passed.

AT the Assizes held at Liverpool on the 9th ult., before Mr. Justice LAWRANCE, SAMUEL CRAWFORD, aged nine, and ROBERT SHEARON, aged eight, were placed at the bar charged with the murder of DAVID ECCLES, aged eight years and a half. From the evidence, as given in *The Times* of the 10th ult., it appears that on Sept. 7th SHEARON had played truant, and that as a punishment his mother deprived him of his clothes, locked him up, and ordered him to remain in bed. She had occasion to leave the house, and on her return she found that he had gone out without his clothes. He was seen by a witness with a portion of a coat over his shoulders and an old sack wrapped round his loins. The statements made by the two boys after they were in custody show that they lifted the deceased over the hoarding of some unfinished and abandoned buildings, in the excavated cellarage of which water had collected, the enclosed waste ground being used by boys for romping and playing purposes. They then asked him to go on the plank; they then pushed him off into the water, then dragged him out and took the clothes off him and pushed him in again twice. He fell face downwards in the water. CRAWFORD got on his head and kept him under for five minutes, and waited to see whether the lad stirred. They then took the boy's clothes and threw his boots into the pit. The prisoners wanted to steal the lad's clothes. That night SHEARON went home wearing clothes which were identified by the mother of the deceased as having been worn by him on Sept. 7th. The next day the body of ECCLES was found lying in the water in the basement of the unfinished building face downwards, naked and dead. After the finding of the body, inquiries were made which resulted in its identification, and publicity led to the mother of SHEARON giving information to the police which implicated the boy in the matter. The prosecuting counsel, after detailing the facts, said that the law as to the capacity of infants to commit crime, though clear, was perhaps not very exact. Up to seven years of age a child was incapable of committing crime. From seven to fourteen the question would be, Did they know the nature and quality of the act? The nearer seven years the more exact and precise the proof of such knowledge and malice must be. The counsel for the prisoners submitted a twofold defence: first, that it was not made out that the prisoners took the life of the lad ECCLES; and secondly, supposing the jury arrived at the finding that they did, then his defence was that the boys were not conscious of the nature and quality of their acts and of their moral gravity. The learned judge, in summing up, approved the

Digitized by Google

law as stated by counsel: between seven and fourteen the prosecution must prove that the prisoners were capable of committing crime by some indications of knowledge or cunning.

Eventually both CRAWFORD and SHEARON were found to be guilty of having committed the act, but not to be responsible on the ground of their youth. It is further stated that the judge entered the finding as "Not guilty." We are told that the prisoners looked quite infants, and that SHEARON'S head hardly topped the front of the dock.

To be "not guilty" under such circumstances could only be the result of privilege, and fortunately, by an arbitrary rule as to age, the law is able to preserve its dignity without perpetrating an outrage upon common sense and popular feeling. Yet it was not always so: for Sir MATTHEW HALE gives two instances where the death penalty was exacted before puberty. One case was that of a girl of thirteen who was burnt for killing her mistress, and the other was that of a boy of ten, who was hanged for killing his companion. BLACKSTONE gives an instance in the last century where a boy of eight years old was tried at Abingdon for firing two barns, and it appearing that he had malice, revenge, and cunning, he was found guilty, condemned, and hanged accordingly. In more modern times a boy of ten was convicted on his own confession of murdering his bedfellow, there appearing in his whole behaviour plain tokens of a mischievous discretion.

According to the law of England, in order that an act may be criminal it must be done by a person of competent age. BLACKSTONE says that infants under the age of discretion ought not to be punished by any criminal prosecution whatever. With regard to capital crimes, by the ancient Saxon law the age of twelve years was established for the age of possible discretion "when first the understanding might open," and thence till the offender was fourteen it was *ætas pubertati proxima*, in which he might or might not be guilty of a crime, according to his natural capacity or incapacity. Under the age of twelve it was held that he could not be guilty in will, neither after fourteen could he be supposed to be innocent. Since the time of EDWARD III. the law appears to have been more desirous to measure the capacity of doing ill or contracting guilt by the delinquent's understanding and judgment rather than by any specific age after the age of seven was reached. Under seven years of age an infant cannot be guilty of felony, for then, as BLACKSTONE says, a felonious discretion is almost an impossibility in nature; but at eight years old he may be guilty of felony. The same author says that under fourteen, though an infant shall be, *primâ facie*, adjudged to be *doli incapax*; yet, if it appear to the court and jury that he was *doli capax*, and could discern between good and evil, he may be convicted and suffer death.

In relation to the question of responsibility, according to the French criminal law, there does not appear to be any age at which a child is absolutely exempt from punishment. If an offence be committed under the age of sixteen, and it be found to have been committed "without discernment," the offender is to be acquitted; but, according to circumstances, he is to be returned to his relatives, or placed in a house of correction, to be brought up there and detained for any number of years not exceeding his twentieth. By the criminal code of the German empire, a person cannot be criminally prosecuted for any offence committed before he ha completed his twelfth year.

In his "History of the Criminal Law of England" Sir JAMES STEPHEN expresses himself as follows:—"By English law children under seven are absolutely exempt from punishment, and from seven to fourteen there is a presumption that they are not possessed of the degree of knowledge essential to criminality, though this presumption may be rebutted by proof to the contrary. Like most other presumptions of law, this rule is practically inoperative, or at all events operates seldom and capriciously. My own opinion is that the age of complete irresponsibility should be raised, say, to twelve (except in the case of a few specially atrocious crimes), and that it should be succeeded by complete responsibility." This definite expression of opinion by an authority of such eminence and experience must carry great weight.

There are many points in the Liverpool case of CRAWFORD and SHEARON that are of deep interest from a psychological and social standpoint, the question of conspiracy between two delinquents being not the least. We shall take an opportunity later on of referring again to this case. Meanwhile we may be allowed to express a hope that, as the boys have been sent to homes with the sanction of their mothers and under the enlightened rule of modern law, their future life may not be overshadowed by reflections of their recent experience, and that their future behaviour may be such as to justify the steps that have been taken for their welfare.

THE opening of the fever hospitals last year for the purposes of clinical instruction and study was an event of the highest importance to medical education, and it did not come before it was required. The want of due provision for teaching the diagnosis and management of the common infectious fevers of the country had for several years been a source of great anxiety to all thoughtful teachers of medicine, and it was felt not to be without grave risk that so many students were placed upon the Register who were almost, if not entirely, without experience and knowledge of this most important part of their work. In former years, when all cases of fever as they came were admitted into the general hospitals, students had ample opportunity of gaining the requisite knowledge; but when in the course of time the general hospitals decided no longer to admit such cases, students had to seek their knowledge elsewhere, and they found that at the only places—viz., the fever hospitals—where the necessary experience could be gained the doors were closed against them, and, strange to say, by Act of Parliament.

A clause in the Poor Law Act of 1867 permitted the fever hospitals as well as the infirmaries to be used for the purposes of clinical instruction and study; but in 1869 this clause was withdrawn and a prohibitory clause introduced. How and why it is difficult to ascertain. It is, at any rate, satisfactory that no one can be found now to acknowledge the responsibility for this retrograde step.

In 1890 the College of Physicians, with the cordial coöperation of the Metropolitan Asylums Board, under

Digitized by Google

whose management the fever hospitals of the metropolis are, approached the Government, and succeeded in obtaining from Parliament the abolition of the prohibitory clause. Rules and regulations against the carrying of infection were drawn up by the College of Physicians and adopted by the Metropolitan Asylums Board. Classes under the direction of the superintendents of the various fever hospitals were arranged for and have been successfully held, but up to the present not largely attended.

It is to be hoped that before long a course of instruction in the diagnosis and management of fevers will be an essential part of medical education and a condition *sine quâ non* of registration. At present attendance on such a class is merely voluntary, and amid the press of work there is a danger that what is not insisted upon will be regarded by the student as of comparative unimportance, and be neglected. A great deal, however, can be done if teachers of the different schools will take the trouble to bring prominently before their pupils the absolute necessity of such a course, and experience proves that where this is earnestly done students will be ready to act upon the advice given. Thus, out of twenty students who attended the courses during the few months that the fever hospitals have been accessible to them, no less than sixteen came from one school, while not one of nine of the metropolitan schools sent a single student. This is doubtless due to the fact that the importance of attending these courses was not brought home as it should have been to the students, who are, as a rule, ready enough to take good advice when it is given them by those they regard. It is earnestly to be hoped that in this coming year all the schools will do their duty equally in this respect.

The need of such instruction in fevers at the present time is self-evident, and the want of proper knowledge is amply shown by the figures recently laid before the Asylums Board. From these it appears that the mistakes in diagnosis during the past twelve months were far above a permissible percentage.

With the Compulsory Notification Act in force the consequences of error become more than ever serious alike to the medical practitioner, the patient, and the public. To the public failure in recognising an epidemic disease, such as scarlet fever, or, still more, small-pox or typhus, may mean not only widespread diffusion of the disease and the loss or damage of many lives, but also, what Boards and Vestries least of all forgive, great expense to the district. On the other hand, to the patient the diagnosis of some infectious fever wrongly may mean the exposure of that patient to great risk of infection, with possible loss of health or life; while in either case the reputation of the medical attendant must seriously suffer when the consequences of his error are so publicly known.

The fever hospitals of London provide ample material even should every student be compelled to take the prescribed course of instruction. There are something like 10,000 cases annually in the six hospitals under the management of the Asylums Board. At each of these hospitals the necessary arrangements have been already, or will be shortly, completed. Three, at any rate, are at the present moment in full working order—viz., the Eastern, the South-Western, and the Western; and at these provision is made for a succession of courses of instruction of two months' duration, according to the number of students applying. The course consists of three demonstrations weekly for a period of two months, at the end of which time a certificate is given if the attendance has been satisfactory. This certificate, it is needless to say, cannot fail to prove of the greatest value to the holder when presenting himself as a candidate for public appointments. The times of the demonstrations are so arranged that they interfere as little as possible with ordinary hospital work. Explicit rules have been carefully drawn up so as to reduce to a minimum the risk of carrying infection to others. These rules are strictly insisted on, and any breach of them would involve serious consequences to the student at his own school. All that a student need do if anxious to attend these courses is to obtain from the dean of his school a certificate or statement that he is of such standing as to be eligible, and to present himself with the certificate at the office of the Asylums Board, Norfolk House. Here, on payment of his fee, he is given the choice, as far as possible, of the particular fever hospital he would prefer, he receives a card stating the days and hours he must attend, and a copy of the rules and regulations to which he is subject, and, at the end of his course, he receives a certificate signed by the officer who has instructed him. The material at these hospitals is enormous, the instruction excellent, and everything has been done to render study there profitable and convenient. The profession owes a debt of gratitude to the committee of the College of Physicians for their energy in raising the whole question, in thrashing out the details of the scheme, and in obtaining the necessary Act of Parliament. It owes very much also to the managers of the Metropolitan Asylums Board for the public spirit they displayed, for their cordial coöperation, and for the despatch with which the necessary arrangements were completed. It would be a disappointment to both of these bodies if full advantage were not taken of the opportunities now offered to the profession. The more students there are, whether qualified or not, at the fever hospitals, the better pleased the managers will be; and should increasing numbers demand increased accommodation, it will doubtless be forthcoming.

The course of instruction in fever will probably ere long be made compulsory, and rightly; for, under the Notification Act, the first duty a student may be called upon to discharge after qualification may be to make a diagnosis of one of the fevers, with all the responsibilities this diagnosis carries with it, and all the risks to himself and the public which an error involves. Formerly medical students were taught the diagnosis and treatment of the common infectious diseases during their apprenticeship, and one of the most important parts of a medical man's education has undoubtedly suffered from the changes caused by the medical legislation of the past twenty years, which no longer compels them to follow such a course. The necessity in the interests of the public of making a course of instruction in fevers compulsory is consequently generally acknowledged, and this will doubtless soon be done; but so long as the course remains voluntary it is to be hoped that the teachers at the metropolitan schools, upon whom the responsibility of directing the instruction of the students rests, will do the duty which is clearly theirs in urging

Digitized by Google

upon the students the wisdom and necessity of acquiring as complete a knowledge as possible of the infectious fevers before assuming the responsibilities of practice.

Annotations.

"Ne quid nimis."

THE QUEEN'S VISIT TO HYÈRES.

HER MAJESTY THE QUEEN has elected to visit this year the oldest of the Riviera health resorts. Long before Cannes and Nice were known to fame Hyères was frequented by invalids and persons of delicate health. It has always been a quiet place, where people went for health rather than for enjoyment. But to those who find their pleasure in the beauties of nature, Hyères, by reason of its climate, its vegetation, and its numerous attractive surroundings, will afford many inducements and much relaxation. Hyères is at once the most southerly and yet the nearest of the French winter resorts. It is situated on latitude 49·7° North, and is sheltered by the Maurettes and the Maure mountains. Dr. Williams mentions eighteen different flowers that bloomed earlier at Hyères than at Cannes, and it is from the Hyères market gardeners that the first spring vegetables reach the Paris market. The climate of Hyères is more sedative than that of most of the Riviera resorts. The town stands at a distance of about three miles from the sea, and thus its inhabitants escape alike from the exciting and sometimes injurious effect of exaggerated dryness and from the saline breezes of the Mediterranean. Many patients who cannot sleep at Cannes or Nice enjoy good repose at Hyères. But Her Majesty proposes to stay at a little distance from the town, and much nearer to the sea. Indeed the climate of Costebelle is very different from that of Hyères. The district known as Costebelle is on the summit of a low range of pine-clad hills, whilst Hyères is at the foot of a precipitous rock. At Costebelle there is the balsamic influence of the pine trees and the more stimulating air, due to its higher position and its proximity to the sea. Hyères is a small place, but Costebelle is simply a hill and a wood, with two hotels on the summit, and a few villas dotted here and there. Sanitation, in such a country district, assumes its simplest form; but, as nearly all the visitors to Costebelle are English, doubtless good care has been taken to adopt the best available measures for the preservation of health. The country around is rich in vegetation and in points of view that constitute the object of delightful excursions, and there is every reason to believe that Her Majesty will be well satisfied with Hyères and its neighbourhood.

INFLUENZA.

THE record of the past week shows no abatement in the influenza generally, for although it is leaving some districts in this country it is invading other parts. Thus it is abating in Scotland, Aberdeen being one of the last places to be its seat; and Dr. Matthew Hay, the medical officer of health, in his report to the town council, strenuously urges the adoption of measures of isolation. In Newcastle and the vicinity it still persists; indeed, one feature of this outbreak, as contrasted with that of two years ago, is the length of time in which the disease seems to linger in one locality. Thus it has not yet ceased to occur in Cornwall and Devon—where the earliest cases of this present epidemic arose,—and it has been conveyed to the Scilly Isles, where almost all the inhabitants have suffered. The affection at the present time is very rife in East Kent—Canterbury, Dover, and Folkestone being especially centres of it. From Dover, indeed, comes a report that the local authorities have imposed a fine of £5 upon any one suffering from influenza who exposes himself in a public place. We fear this measure — if it really be taken — will not do much to limit the spread of an affection which, though admittedly contagious, is also, according to high authorities, miasmatic. It is also prevalent in Bedfordshire. The metropolis is still free from any severe outbreak, but that influenza has a certain foothold in London is seen by the fact that during the week ending Dec. 26th nineteen deaths were directly attributed to it, an increase of two over the preceding week. The mortality from diseases of the respiratory organs last week in the metropolis was greatly in excess of the average—no doubt owing to the prolonged fogs,—and the total death-rate rose to 21·9. In Newcastle last week the death-rate was as high as 45·1 per 1000. Abroad influenza has appeared in Italy, epidemics being notified at Rome, Turin, Florence, Milan, and Bergamo. It is said not yet to be really epidemic at Vienna, although several sporadic cases have occurred there, and it is increasing steadily. There has been an outbreak on board H.M.S. *Dreadnought* at Malta. At New York it is averred that the disease has attacked the monkeys in the zoological collection there.

DEATH OF PROFESSOR JOHN WOOD.

WE regret to announce the death of Professor John Wood, F.R.S., which took place at his residence in Wimpole-street on the 29th ult. Arrangements have been made for the funeral to take place at Kensal-green on Monday, Jan. 4th, at two o'clock. Mr. Wood's professional life was spent at King's College and King's College Hospital. In 1846 he entered the medical department of the College, in 1851 he was appointed Demonstrator of Anatomy, in 1870 Professor of Surgery in succession to the late Sir Wm. Fergusson, in 1777 joint Professor of Clinical Surgery with Sir Joseph Lister, and in 1889, on his resignation, he was made Emeritus Professor in King's College and Consulting Surgeon to King's College Hospital on account of his valued services to those institutions.

A NEW AND POWERFUL LIGHT.

A VERY intense light, such as is required for photographic or occasionally for medical purposes, may, as is well known, be readily obtained by burning magnesium ribbon, which has, however, the disadvantage of being somewhat expensive. An excellent substitute has been found by a French chemist, M. Villon, in aluminium, which is about a third of the price of magnesium, and which may be utilised in the same manner by burning it in a spirit lamp, or, if a flame of much more intense brilliancy is required, in a coal, gas, or spirit flame supplied with a jet of oxygen. In these it burns without emitting fumes, in which respect it is superior to magnesium. The light given by aluminium has a high actinic power—nearly as high, indeed, as that of magnesium. The most convenient way of obtaining a very intense light, according to M. Villon, is to use a lamp provided with a jet of oxygen at the centre of its flame, into which powdered aluminium mixed with a quarter of its weight of lycopodium and a twentieth of its weight of nitrate of ammonium can be projected by means of a tube furnished with an air-ball. This gives an exceedingly intense light, without smoke. A mixture of aluminium powder with chlorate of potash and sugar can be ignited, giving an intense light by means of gun-cotton, but is somewhat dangerous. Probably the best plan for medical photography, or for laryngoscopic and auroscopic and other demonstrations, would be to burn

Digitized by Google

a ribbon of aluminium in an ordinary spirit lamp. Of course, if oxygen and an oxy-hydrogen, or a oxy-alcoholic, lamp were at hand a much more intense light could be obtained.

THE ACCIDENT TO PRINCE CHRISTIAN.

WE have received the following from an official source:—On Saturday, Dec. 26th, H.R.H. Prince Christian, whilst shooting in the grounds of Osborne, was struck in the left eye by a shot. He was at once seen by Dr. Reid, who, finding that the shot had penetrated the globe, telegraphed for Mr. Lawson. On the following morning (Sunday) Mr. Lawson, assisted by Dr. Reid and Dr. W. Hoffmeister of Cowes, removed the injured eye. The Prince has progressed very satisfactorily. The anæsthetic used was the A.C.E. mixture.

DOES ETHER ASSIST DIGESTION?

THE effect of ether on the digestive processes in healthy subjects has been recently investigated by Dr. Gurieff, who gave thirty drops of sulphuric ether to six healthy persons during dinner, which consisted of about half a pint of soup, four ounces of meat, and six ounces of bread. It was found that the ether had the effect of stimulating the action of the gastric glands, increasing the free hydrochloric acid in the gastric juice, and causing the peristaltic movements of the stomach, together with its power of absorption, to increase thus; on the whole exercising a favourable effect upon the gastric digestion. The same result was obtained when the ether was administered by means of hypodermic injections. It would appear, therefore, that the effects must be ascribed to a general rather than to any merely local action on the mucous membrane of the stomach. Dr. Gurieff is disposed to think that there is a stimulation of the cephalic centres. This view is partly based on the observations of other Russian observers—Bekhtereff and Miloslevski, and Pavloff and Shumova-Simanovskaya—on the dependence of the gastric functions upon the central nervous system.

SANITATION AT FLORENCE.

SIR DOUGLAS GALTON, in his report on the sanitary condition of Florence, confirms in every sense the description given of the sanitation of Florence by our special commissioner, which we published on Jan. 7th, 1888. Our commissioner, like Sir Douglas Galton, did not find fault with the public water-supply of Florence, but he denounced the continued use in some houses of private well water. It was with regard to domestic drainage that the greatest complaint was made. Untrapped, unflushed closets, porous drain-pipes, and abominable cesspools, often ventilating into bedrooms or kitchens, were described and declaimed against. Our commissioner sent drawings of the main sewers—big, awkward structures, with broad, flat inverts, and insufficient means of flushing. He also mentioned that some of the newer sewers were being built in the egg-shaped and modern manner. We are glad to hear that the number of these latter has been increased since the publication of our commissioner's report. But, still, the fundamental grievances which he denounced four years ago seem to remain. The question of domestic drainage is neglected now as in the past, and is "sufficient to account for the spread of typhoid fever." On the other hand, the quarters of the town where new drains have been built and where the house sanitation has been improved escaped from the recent epidemic of typhoid fever. Thus the complaints we made, the warning we gave, at the commencement of the year 1888 have been entirely justified by the events which have since occurred, and by Sir Douglas Galton's recent report. We trust therefore that the municipal authorities of Florence will take action. We know that their position is exceptionally difficult. Once capital of Italy, but now reduced to the level of a provincial town, Florence has greatly suffered as respects her local budget, and doubtless the municipality would do more if it only possessed the financial means. But much good sanitary work can be accomplished without very large outlay; and the interior condition of houses could be altered mainly at the expense of the owners. In this respect, the municipality of Florence cannot do better than follow the example of the municipality of Brussels, where the same difficulties have been overcome in a most radical and successful manner.

FIRST AID BY CHEMISTS.

WHEN a person meets with an accident in the street it is a common practice to take him to the nearest chemist's shop; and this custom prevails not only here, but in other countries, where the laws against counter-practice are much more definite and severe than with us. In the Argentine Republic regulations are actually laid down for the guidance of pharmacists under such circumstances. Only the proprietor of the shop may attend to accidents, and he only to those which are quite recent. For washing the wound he must use either a 4 per cent. solution of boracic acid or a ½ per cent. solution of salicylic acid. No sponges may be used, but only pieces of absorbent wool. Hæmorrhage must be arrested by pressure with moist cotton wool or by compression of the artery. The edges of a wound are to be drawn together, but not completely so, by sticking-plaster; over this a layer of cotton must be put, and the whole retained by a gauze bandage. When there is a loss of substance, so that the edges of the wound cannot be brought together, the wound must be sprinkled with iodoform to the thickness of about half a millimetre. Burns are to be covered with cotton or linen soaked in carron oil. In simple fractures strips of cardboard covered with cotton wool are to be applied. No other substances—such as carbolic acid, perchloride of mercury, or amadou—and no charpie or calico bandages are on any account to be applied to wounds by the pharmacist, who must be careful to tell the patient to get the advice of a doctor as soon as possible. How would our chemists like to be obliged to conform to regulations of this character

FROST, FOG, AND SMOKE.

THE connexion between frost and fog, and its mischievous capabilities, have seldom known a more striking illustration than that afforded by the weather conditions which prevailed last week in the metropolis. To much public and private inconvenience of other kinds we must add the injury sustained by trade at a season which is for many shopmen the busiest in the year. Custom lost at such a time is not recovered, and we may regard it as certain that the Christmas takings for the year just ended would show on examination a depression markedly related to the suffocative gloom which a few days ago enshrouded the city. This, however, is but a secondary circumstance in comparison with other and more directly vital consequences. The loss of life primarily due to the fog has been considerable. Last Thursday week no fewer than eight inquests were held upon the bodies of persons who had been drowned in the docks from sheer inability to see their way. In no instance was there any reasonable suspicion either of suicide or intoxication. Four of the eight men who thus perished moreover were dock employés, and therefore presumably familiar with the roadway under ordinary conditions. The obvious necessity of such an arrangement of chain-barriers as would prevent similar accidents in future should not require

Digitized by Google

to be impressed upon dock authorities. We give in another column some statistics of fracture and contusions which by the courtesy of the secretaries we have been able to obtain from the various metropolitan hospitals—casualties largely attributable to the causes already mentioned. The marked prevalence of asthma and bronchitis may also fairly be traced to the same sources. Every practitioner has lately had occasion to deal with cases of this trying and dangerous malady. What is of especial importance after its cure, if present, is the prevention as far as possible of the cause to which both it and the accidental deaths we have recorded are mainly attributable—the fog. Of late the press has been fruitful of suggestions respecting this matter. All of course agree in condemning the ordinary coal fire, which is a main source of mischief, and it must be admitted that some of the substitutes proposed in its place bear the mark of practical intelligence. The well known utility of gas for heating and cooking purposes requires no commendation where conditions admit of its employment. Unfortunately, there frequently exists a serious difficulty as to this during frosty weather. Otherwise no better preventive of the fog atmosphere could be found. It is possible, however, even while using coal, to use it in such a form and way as materially to diminish its power of smoke production. For this purpose a non-bituminous coke or anthracite is clearly preferable, and is capable of imparting great heat if the grate be furnished with firebricks in the manner suggested by Dr. George Wyld Most of our readers are familiar with the construction of the slow fire which burns from above downwards, the draught from below being stopped by a metal plate. By the use of either of these methods it is possible to maintain a fire suitable for all ordinary purposes, and possessing an obvious advantage in the fact that it certainly emits a much less than ordinary volume of smoke. It has been proposed that the duty of smoke consumption where coal is burnt should not be enforced in the case of manufactories only, but that the larger kitchens of clubs and hotels should be equally liable. The suggestion, if novel, is certainly reasonable enough. It is, indeed, unquestionably desirable. Whatever the method most approved, however, it must be allowed that the time has come when every possible effort should be made to abolish the fog-tyranny with which we have been in so recent and ruinous association.

TUBERCULIN AT THE BROMPTON HOSPITAL.

A REPORT has been issued from the Hospital for Consumption and Diseases of the Chest, Brompton, upon the results of the treatment of cases of phthisis and lupus by tuberculin. The remedy was used systematically for four months from Dec. 6th, 1890, to April 5th, 1891, during which time 30 patients were so treated; 28 of these were phthisical (18 males and 10 females). The report gives in a succinct manner information of the nature of the cases, the condition of lungs and expectoration, the number of the injections and their results as to reaction, temperature, cough, and expectoration, changes in physical signs, in general condition, and in body weight. It is stated that 15 improved under the treatment, or 53·6 per cent.; one was stationary, and 12 grew worse (3 deaths), or 42·8 per cent. As to weight, 53·5 per cent. gained in this respect, 14·2 per cent. were stationary, and 32·1 per cent. lost weight; but this result is qualified by the fact that the cases were selected for their being either early or limited in character and extent. The reporters admit that tuberculin speedily causes inflammatory changes in and around tubercular lesions, thus promoting the formation of cavities, as proved by the appearance of lung tissue in the sputum and by cavity signs replacing those of consolidation. It increases the amount of expectoration, but there is no proof of its diminishing the number of bacilli in the sputum; in some cases they apparently increased under its use. In many cases the injections were followed by signs of distinct extension of the disease. The "reactions" were exhausting, and caused loss of weight and strength. "The treatment is specially contraindicated in lung tuberculosis accompanied by pyrexia, as likely to convert intermittent into continuous pyrexia." In two cases there was evidence of fibroid contraction of cavities accompanying the use of tuberculin. The final judgment is—"That the tuberculin did not favourably influence the course of the disease in the majority of cases; that in some the effects were detrimental; and that even in the stationary and improved cases it was difficult to ascribe any distinct improvement to the injections, which might not have been equally attained under the treatment ordinarily employed in the hospital." The report is signed by Drs. Theodore Williams and Tatham. A report on two cases of lupus treated by tuberculin is appended by Mr. Godlee. Both cases "showed marked temporary improvement, followed by a return towards, if not actually to, the condition preceding the commencement of the treatment, when the injections were stopped; and that even before stopping the injections, the retrogression had already set in."

EXPLORATION OF KAFFIRISTAN.

HEROISM has been so connected with deeds of valour in the battle-field that we are apt to overlook that higher heroism which is the innate result of self-sacrifice undertaken for the advancement of science and for the benefit of mankind. The Indian correspondent of the *Daily Chronicle* records such an instance in the case of the explorations in the wilds of Kaffiristan by Mr. G. S. Robertson, Agency Surgeon at Gilgit. "His experience among that hitherto mysterious people will be most interesting and valuable. At one moment an honoured guest, at another surrounded by crowds of frantic savages clamouring for his blood, he established his supremacy by the calm audacity which distinguishes the British race. Armed with no authority, backed by no escort, but relying solely on his own determination and coolness, he has been the first British subject to explore that wild country."

SEWERS OR CESSPOOLS FOR CHICHESTER.

THE Corporation of Chichester seems likely to adopt a very retrograde step—namely, one which will tend to perpetuate a system of leaking cesspools, instead of adopting a method of sewerage for the city. One of the members of the Corporation is alleged to have stated that with a cesspool the only danger is that "occasionally the air is made to smell a bit," and this in a town where the contents of 2440 privy-pits and cesspools are allowed to soak away into the soil on which the place is built, and where about 816 houses are dependent for water on wells sunk in this soil. Then, again, it was advanced that cesspools can be kept out of houses, whereas "sewers had to be laid under them." Whether house drains pass to cesspools or to sewers, the only difference in this respect lies in the fact that since the cesspool must almost always be constructed on the premises to be drained, whilst the sewer is in the public thoroughfare, the sewer is, as a rule, farther away. Moreover, the question of drains passing under a house or not depends entirely on circumstances which are distinct from their outfall being into sewer or cesspool. Views of the above sort were applauded by a number of town councillors, and hence it is not astonishing that they elected to try a system for pumping out the cesspools of Chichester by means of ap-

Digitized by Google

paratus which was adapted only to cesspools containing liquid contents; and to get over the difficulty due to the fact that Chichester retained the more liquid of its cesspool filth in its own soil, it was provisionally announced that before beginning the pumping processes, liquid was to be mixed with the more solid contents of the Chichester cesspits. A final effort to upset such proposals was rejected by one vote. Under these circumstances it is not to be wondered at that, at a subsequent meeting attended by some of the leading medical practitioners of the city, it was decided to make formal complaint to the Local Government Board, under Section 299 of the Public Health Act of 1875, to the effect that the sanitary authority had made default.

ARTIFICIAL TEETH FROM A HYGIENIC POINT OF VIEW.

IT is common experience amongst dentists that a very large majority of artificial dentures worn are discoloured and by no means devoid of unpleasant odour. This lack of cleanliness, which arises sometimes from neglect, but often from want of instruction on the part of the dentist as to the necessary *modus operandi*, is a fruitful cause of inflammatory conditions. Débris of food mixed with saliva and mucus accumulating on a plate rapidly undergo decomposition, with the result of irritating the mucous membrane and producing a general inflammation of the oral cavity. The oral secretions become altered and vitiated, so as to cause dyspepsia, and caries of the remaining natural teeth is set up, which proceeds with great rapidity, especially in "clasp" dentures, not from the friction, but because the inside of the clasps most generally escape the brush. The materials used in the construction of artificial dentures differ widely in their effect upon the tissues with which they come in contact. A larger number of cases of inflammation of the oral tissues occur where vulcanite is used as a basis than with gold or other metals, and so prevalent is this inflamation in the case of vulcanite that it has received the distinctive appellation of "rubber sore-mouth." Several reasons have been assigned for the effects produced by vulcanite. Nearly all this material is coloured with mercuric sulphide (vermilion), which ingredient has been accused of being the cause of trouble; but an exhaustive investigation did not substantiate this view, one particular point being that "rubber sore-mouth" often occurred where black rubber was used, which contains no vermilion. The porosity of vulcanite, especially when not sufficiently vulcanised, renders it liable to retain deleterious material if not kept scrupulously clean.

BURIAL REFORM AND ITS LEGAL REGULATIONS.

THROUGH the courtesy of Mr. Seymour Haden we have again an opportunity of revising his published opinions on the subject of reform in burial as a substitute for cremation. At the meeting of the International Congress of Hygiene and Demography last October Mr. Haden fully explained the advantages of the earth-to-earth system which is associated with his name, and in a subsequent letter to *The Times* he ably defended the propositions laid down in that paper. Notwithstanding that we have already on several occasions discussed this question, the practical importance of certain points which are noted in the articles before us must be our justification for again referring to them. Much has been said by cremationists respecting the contamination of water-supply by filtration of putrefactive matters from adjacent burial grounds, and the subject is unquestionably one deserving the cautious consideration of sanitary authorities. We are constrained, nevertheless, to the belief that under all ordinary conditions the oxidising processes occurring within the soil are sufficient for the wholesome transformation of such noxious substances into relatively harmless chemical equivalents. The now familiar instance of the Bishopsgate pump may be quoted in illustration. In dealing with morbid infection the case is somewhat different. Here again we cannot doubt that Nature is equal to the work of purification if due freedom, time, and earth space be allowed her processes. As regards time, difficulty may sometimes arise, and the observations of Pasteur and others tend to show that the germs of disease may linger long in the soil in which infected bodies have been buried. Such a contingency is of course abnormal, and it is one which could be simply and effectually met by the use of antiseptic precautions. As regards the medico-legal objection to cremation, we have little to add to former observations. Even the very careful system of certification adopted by its advocates is of course not perfect, and, though we would not go so far on this or any other known ground as to advise, with Mr. Haden, the prohibition of the practice, we confess that, in our view, no other method can ever so fully satisfy the possible needs of a criminal investigation as that which allows the exhumation of the body. Let us, in closing, briefly impress four points which comprise the gist of the rules relating to burial reform. These are: (1) That accurate certification be enforced; (2) that burial take place with the least possible delay after death has occurred; (3) that the needful arrangements be of the simplest kind, and such as to ensure virtually direct contact between the soil and the body; and (4) that legislative action be taken to secure these purposes.

A NEW BACILLARY DISEASE.

MM. CAZAL and VAILLARD, in the June number of the "Annales de l'Institut Pasteur" (Sur une Maladie Parasitaire de l'Homme), describe a remarkable condition in a patient who came under their observation. M. P——, a strong, muscular man, aged thirty-three, was admitted suffering from dysentery, dilatation of the stomach, restlessness, with a full pulse, no headache, nothing the matter with the lungs or heart, dry mouth, great thirst followed by extreme diarrhœa, and painful micturition. Eventually the patient died with symptoms very like those met with in the algid period of cholera or in cases of acute poisoning. On the whole of the peritoneal surface, in the pancreas, and in the liver were small rounded, discrete nodules, from the size of a millet seed to that of a pea; these contained a caseous substance, white, yellowish, and fatty, very like that found in dermoid cysts. There was some evidence of peritonitis; the mesenteric glands were slightly enlarged and congested. The nodules were most numerous in the pancreas, which appeared to have been the primary seat of the affection. In the fatty material were small, short bacilli well stained by Loeffler's blue. They were a little longer than broad, had rounded ends, not well stained by Gram's method. In the necrotic areas the masses of bacilli could be distinctly seen; they were also found in the more normal tissue, but they were not to be found in the healthy parts. In cultures, in which it was an easy matter to obtain pure growths, the organism was found as a short, motile rod, which might be isolated, arranged in pairs, or grouped in chains of ten or fifteen, or even more. These chains moved slowly, with a wavy-like motion. Unstained, they had the appearance of a figure of eight, or were dumb-bell-shaped, and were surrounded by a delicate, clear zone, which appeared to be a kind of envelope, though it was impossible to demonstrate the existence of a capsule by staining methods. The organism grows either aerobically or anaerobically. It causes cloudiness in broth after twenty-four hours, forming at the bottom of the flask a thick, pale, flocculent deposit.

Digitized by Google

The supernatant fluid is slightly milky, and gives an alkaline reaction. It grows more readily on the surface of gelatine, and causes slow liquefaction in forty-eight hours; at the bottom of the funnel there is a white, flocculent deposit. Grown on the surface of agar there forms in twenty-four hours, at 37° C., a moist, opalescent, translucent growth which extends rapidly until it covers the whole surface with a delicate uniform layer which gradually becomes thickened, though it still retains a certain amount of transparency. On potato the culture is abundant and spreads rapidly over the surface as a thick, moist, and slightly viscid film, first of a clear yellow colour and then of a yellowish brown. The cultures have a somewhat ammoniacal odour, almost like putrefying urine; they remain active for several months when exposed to the air, but when protected from air and light they remain active for more than three years. This microbe does not appear to form spores; it is destroyed in fifteen minutes at a temperature of 60° C. in a moist medium, but after drying it resists the temperature of 100° C. for about five minutes.

A CASE OF COLOBOMA OF THE OPTIC NERVE WITH SIMULTANEOUS MELANOMA OF THE CILIARY PROCESS.

DR. TALKO publishes in the *Przeglad Lekarski* the case of a boy of five years old who, from his birth, had been suffering from considerable impairment of sight. He discovered in both eyes a coloboma without a vestige of the hyaloid, and a melanoma of the ciliary process as well, the first case of the kind he had seen in his ophthalmic practice of thirty years. No such case has, as far as he knows, ever been mentioned in medical literature. Dr. Talko is not certain if the embryonic deformity of the ciliary processes is merely a complication of the coloboma, or whether it may be found independently of other deformities of the eyeball. The case, as the first of its kind, certainly deserves to be recorded.

FOOD SURVEILLANCE IN ITALY.

AMID so much (writes a holiday contributor) that calls for redress in the sanitary state of Italy, it is gratifying to record the energy and success with which her food and drink-supply is safeguarded. Shortly after the Public Health Act came into force one could hardly open a newspaper without alighting on paragraphs announcing the seizure of adulterated breadstuffs, or tainted meats, or "doctored" wines, or bogus mineral waters. Some of the great industries, like the sausage manufacture at Bologna, were severely compromised by the exposure of the semi-putrid horseflesh used in it; the cheese producers of Lombardy were also shown to deal largely in counterfeits; and the confectioners, with their brightly coloured dainties, and the "liquoristi" (or fancy-drink vendors), with their seductive beverages, were often convicted of employing deleterious and even dangerous substances to enhance the attractiveness of their wares. The penalties inflicted on these offenders, however, were so exemplary that few now venture to enrich themselves at the expense of the public and in contravention of the law; and the notoriety given to them in the press brought such custom to the "fair and square" dealers as to make many new, if tardy, converts to the principle that honesty is the best policy. Such cases, indeed, as the following become rarer and rarer, while the occasional publicity given to them serves to keep up the deterrent force of the act. A fancy baker in Turin was convicted of using a noxious dye to give an attractive colour to the "tortellini" (pastry with sweetstuff inside), for which Turin is famous. In spite of his plea that he did not know the deleterious nature of the colouring matter in question, the baker was sentenced to five days' imprisonment and twenty lire (16*s.*) fine. Against this sentence he appealed; but the Court not only sustained the judgment already given, but, finding that the adulteration had been practised in full knowledge of its hurtfulness to the consumer, and with the clear object of enhancing the selling price of the article, condemned the appellant as an "adulteratore doloso" (fraudulent adulterator), and gave him five months' imprisonment, with a fine of seventy-three lire (£2 18*s.* 4*d.*). Italy does well to protect the consumer by such stringent regulations, and if she continues to practise the same surveillance over other matters equally affecting the health of the community she will have no reason to complain of the abstention of foreign visitors from her "sun traps" or winter cities.

A GASTROLITH IN MAN.

DR. KOOYKER has reported in the *Zeitschrift für Klinische Medicin* another case of gastric calculus—a condition which, though common enough in animals, is so rare in man that so far only seven cases have been reported. Dr. Kooyker's case was that of a man fifty-two years old, in whose lifetime it had been impossible to make a positive diagnosis, though some neoplasm of the stomach was suspected. The patient died from exhaustion. At the post-mortem examination a concretion was found in the stomach, almost entirely filling its cavity, which weighed 885 grammes and was eighteen centimetres in length. The microscopic examination resulted in finding starch, vegetable cells, chlorophyll, and vascular tufts, while hair and other animal elements were entirely absent.

"THE LANCET" RELIEF FUND.

UPON another page will be found the third annual report of the Almoners of this Fund, from which it will be seen that relief has been afforded in twenty-two cases, eight being cases in which money was advanced by way of loan and fourteen cases in which gifts of money were made. In number the total is precisely equal to that of the preceding year, the distribution of the benefits having also been an almost exact reproduction of that which was reported in 1891, when the loans were seven and the gifts fifteen in number. In amount the grants have this year been slightly larger than last year, the loans having aggregated to the same total sum—£117—and the gifts to £11 more than in 1890. The correspondence, of which some extracts are given in the report, shows that the facility with which in a proper case a grant can be made from this fund renders it in a case of emergency, such as it is intended to meet, a most valuable resource to the victims of sudden and unforeseen misfortune. Indeed, in many of the cases which come under the notice of the Almoners it is not merely true that *bis dat qui cito dat*—this aphorism does much less than justice to the facts, for in such circumstances as we have now in view to delay is to withhold, and he only gives at all who gives at once. It is a great satisfaction to the donors and Almoners of the Fund to know that so far it has proved fully equal to the particular class of necessities which it is intended to meet, and no single suitable case has been refused relief for want of funds. The balance in hand has steadily grown from year to year; and from £125 19*s.* 6*d.*, at which it stood in the beginning of last year, it had accumulated by the 31st December last to £170 14*s.* Although, therefore, it has been necessary to refuse some applications, every such refusal has been grounded on the demerits of the application, and no case coming within the rule has yet been brought to the notice of the Almoners without obtaining relief. We

Digitized by Google

have, therefore, no difficulty in calling the attention of our readers to this charity. The Almoners can, of course, only deal with cases that are actually brought to their notice. Their satisfaction in having been able, so far, to deal in a suitable manner with every such case is founded upon a hope that the general diffusion of information concerning the existence of this Fund leads to their receiving in every, or almost every, fitting case an application for relief. A form to be used in making applications for grants will appear in next week's issue of THE LANCET. We would call attention to the fact that Mr. Edward Davies has been appointed Secretary to the Fund, and that in future, as will be seen on reference to the form of application, all communications should be addressed to him at THE LANCET Offices, 423, Strand, London, W.C.

SENSORY AND VASO-MOTOR DISTURBANCE IN FACIAL PARALYSIS.

DR. FRANKL BOCHWART, in an investigation into the conditions present in twenty cases of facial paralysis, found that in three there were disturbances of sensation and of the vaso-motor functions, in five of sensory functions only, and in two of vaso-motor only. The sensibility was only affected to a very slight degree, and sometimes the mucous membrane on the tongue and inside the cheek was affected, and sometimes it was not. Occasionally also taste was affected. These sensory phenomena disappeared much earlier than the paralysis, but in one case in which the paralysis persisted there was diminished sensibility even after several years. The conclusion sought to be drawn from these facts is that the facial nerve in man contains some sensory and vaso-motor fibres; but of course it would first have to be shown that the fibres of the fifth nerve had not also suffered when the facial nerve became affected.

DIPHTHERIAL INFECTION OF TRACHEOTOMY WOUNDS.

DR. SPRONK of Utrecht[1] has discovered in the case of three children who had been tracheotomised for diphtheria a condition which has not hitherto been described, but which he thinks is far from rare. This consists in an inflammatory œdema of the subcutaneous and fatty tissue around the tracheotomy incision, caused by the invasion of diphtheria-bacilli. He points out that in ordinary diphtheria the bacilli are confined to the epithelial surface and the false membrane, and never penetrate into even the uppermost layers of connective tissue so long as the mucous membrane is free from necrosis. Nor are the bacilli ever found in the internal organs and blood of infected individuals. Nevertheless it has been shown experimentally that these microbes can multiply in the subcutaneous tissues, especially of some animals, guinea-pigs for example. The cases he examined had died a few days after tracheotomy, and although the wound itself was free from membrane, and looked healthy, yet there was a more or less widespread diffuse œdema, without any change in the superjacent skin. This œdema was obviously inflammatory, but there was no necrosis. In two cases it occurred not only in the vicinity of the wound, round the trachea and in the intermuscular tissue, but extended for some distance over the chest and upwards to the supra-clavicular regions. He found by tube-cultures that the serum taken from different parts of the œdematous area contained abundant bacilli, which were almost as numerous at a distance from the wound as near to it. The possibility that they may have multiplied after death was slight, seeing that these organisms require a temperature of at least 20° C. to grow. Other bacterial colonies were produced from the serum, but in one case this yielded almost a pure culture of Klebs' bacilli, and the capability of these organisms to cause this type of inflammation was proved experimentally. Dr. Spronk lays especial stress on the fact that, although of course the infection takes place through the tracheotomy wound, yet its margins appeared natural. This he ascribes to the use of iodoform and the short time that elapsed between the operation and death. The importance of the discovery lies in the additional risk of the rapid absorption of the toxine produced by the bacilli when these are lodged in connective tissue.

IMPORTED INFECTIOUS DISEASES AND THE LIVERPOOL PORT.

SOME members of the Sanitary Committee of the Liverpool Corporation are desirous of imposing special restrictions on the landing and removal of cases of infectious diseases reaching their port. The desire is, in one sense, a laudable one, for it is very important to control imported infection. But, on the other hand, such a city as Liverpool should, above all others, remember that any unusual restrictions imposed on shipping and persons reaching our ports, in respect of our current contagious diseases, is a thing that the sanitary authorities of this country have decided to be unnecessary, and one that we generally cry out against when imposed on us in foreign ports. With yellow fever we are still tied to a quarantine system, without having the means of effectually carrying it out; with cholera we have to do with special regulations under the Cholera Order; but when we come to current infectious diseases we have nothing but the ordinary sanitary law and its provisions. Dr. Stopford Taylor has rightly advised that no special danger attaches to the removal of such cases by ambulance from ships in dock to the ordinary infectious hospitals, and his view must be regarded as correct. Such diseases are not, under proper restrictions, a danger by reason of ambulance traffic, and if the proper restrictions can anywhere be applied they ought to be possible with the aid and control of dock and port officials.

INFLUENZA AT MILAN.

WE make no apology for returning to the outbreak of influenza in the Lombard capital—that great entrepôt of the travelling world between West and East. The malady has outgrown the dimensions of an epidemic; it may rather be described as a plague. The public offices, the factories, the stores, the studios—all have the majority of their hands on the sick list and the hospitals can hardly admit another patient. The schools, on reassembling, will hardly muster a fourth of their number, though it is the infant rather than the boy, as it is the old man rather than the adult, that the malady visits most severely. The mortality, not great when we wrote last week, is now considerable, the deaths on Christmas Day amounting to sixty-five. With all this, it is not the influenza of two years ago. It wants the neurosal complications characteristic of its predecessor. Its attack is directed mostly to the lungs, setting up, or more often aggravating, bronchitis and pneumonia. Weak hearts, too, suffer severely under it. Coupled with the pulmonary and cardiac symptoms there is not unfrequently a kind of infective gastritis (*una specie di gastrite infettiva*, as the local physicians call it), characterised by total loss of appetite, while palate and tongue are furred with a paste like that of powdered marble (*poltiglia*), and there are pains at the stomach as in gastralgia proper. Errors of diet in quality or amount—anything that causes indigestion in short—seem to determine the virulence of the disease towards the stomach. In some cases, though by no means in the majority, rapid loss of strength ensues on the fever, though the

Digitized by Google

temperature is rarely above 101° or 102° F. In treatment the best—or rather, the only good—results have been obtained from quinine in varying proportions, or in combination with strychnine. Another feature of the visitation is the extreme liability to relapse, a first attack giving no immunity from subsequent ones, but seemingly inviting them; and these are less tractable than the primary one. An intelligible explanation of the violence of the disease in Italy is given by one of her most experienced practitioners, and that is the defective underclothing of the people, rich and poor alike. This, with the very insufficient warming apparatus in most Italian houses, and the tendency to make up for it—in the lower quarters particularly—by *huddling*, accounts (in his opinion) for the spread of a disease which ought, on many grounds, to find a less favourable nidus in Italy than in more northerly countries.

OPERATION FOR INTRA-CRANIAL HÆMORRHAGE.

DR. STIMSON showed, at a recent meeting of the New York Surgical Society, a patient, forty years of age, who some weeks before had been, in the course of a quarrel, struck on the head with a club. When first seen he was found to have a marked irregularity at the junction of the parietal bone with the squamous part of the temporal on the left side. Weakness of the right leg with complete paralysis of the right arm developed—it is not stated how long after the accident,—and his vocabulary was reduced to "Yes" and "No," although he could make voluble use of expletives. A diagnosis was made of intra-cranial hæmorrhage following injury, and five or six days after the injury was inflicted he was operated on. There was found to be a fracture of the temporal bone above the ear, but no depression. A fissure ran backwards over the parietal border. No blood was found between the bone and the dura, but the latter was dark in colour and no pulsation was observed in it. On opening it a large clot was found in the subarachnoid space extending back a considerable way. An ounce and a half in all were removed and the flap sutured. There was no immediate improvement in the patient's condition, but the paralysis gradually passed away and the ability to talk returned, although there was still evident impairment of this faculty. The case is a very important one, and its progress is very suggestive. Apparently operation could not be undertaken at once, as the question of possible homicide was pending, but there seems little reason to doubt that early operation in such a case would be followed by rapid recovery. Even after five or six days the amount of restoration obtained by the operation must be gratifying both to the patient and the surgeon, and it will no doubt become greater as time goes on. One curious thing about the case is that no mention is made of fits of any kind, which we should have expected as a result of a subdural hæmorrhage such as was present.

THE PREVENTION OF OVERLAYING.

IN the course of an inquiry held at the Marylebone Coroner's Court last week, Dr. Danford Thomas again drew attention to the relatively large number of infant deaths attributable to overlaying. The proportion of such deaths throughout London during the year is, he reminds us, between 600 and 700, and of this total somewhat over 200 are furnished by the central district alone. Dr. Thomas, in the course of his observations, offered a simple and rational explanation of the manner in which the fatal result is commonly brought about. It is due, in his opinion, either to the child slipping under the bedclothes when the mother's arm on which it lies becomes relaxed in sleep, or to its being drawn too near and pressed against the breasts. Either explanation is quite feasible, the former as accounting for mere accidental self-suffocation, such as also occurs when an infant is put to bed closely wrapped in a shawl; the latter as explaining the purely reflex act by which a sleeping parent may turn upon and smother her child. Clearly no person can or ought to trust herself in the circumstances with so frail a life. Cots are not so expensive but that the poorest mother, if thrifty, can usually provide one. If otherwise, even an improvised chair-couch is better for the infant than her own bed. It has been suggested that any case of fatal neglect in this particular should be held as a punishable misdemeanour. There is much to be said for this proposition. Our only objection to it is based upon a reluctance to enforce the penalty of imprisonment with its contaminating influences, and upon a conviction of the greater power of education than of legal rigour as a means of prevention. It is to be hoped and expected that the repeated warnings issued by Dr. Thomas and others in connexion with the subject will be duly regarded, and thus fulfil their intended purpose of instructing public opinion on this important subject.

CONVULSIONS TREATED BY COMPRESSION OF THE CAROTID.

DR. LEOPOLD ROHEIM of Budapest publishes in the *Gyógyászat* a case of eclampsia which he had, after the failure of all ordinary remedies, successfully treated by compression of the carotid. The case, which is quoted by the *Pester Medicinisch-Chirurgische Presse*, was that of a robust man of fifty-six, who had been suffering for years from cancer of the bladder, with occasional hæmaturia. The man had been attacked by a most violent eclamptic paroxysm, which was mainly confined to the left side. Dr. Roheim prescribed in vain musk, valerianate of zinc, bromide of potassium, assafœtida, hypodermic injections of morphia, enemata of hydrate of chloral, and frictions with mustard, and at last employed compression of the carotid. After constant compression for some time of the right carotid the convulsions were suddenly arrested, the patient recovered normal respiration, and very soon felt quite well. Two or three slighter attacks followed, which were soon arrested by properly instructed attendants. The effect of the compression was so remarkable that Dr. Roheim earnestly recommends this treatment. He compressed the carotid with the index and second finger between the larynx and sterno cleido-mastoid muscle backwards towards the spine, just as Trousseau and Bland had recommended. He was equally successful in the case of a girl nine years old. He considers the *rationale* of the treatment to be that by compressing the carotid and at the same time necessarily the sympathetic nerve fibres, which closely follow the course of the artery, the excitability of the brain is allayed.

CARCINOMA OF THE LARYNX.

DR. LICHTWITZ of Bordeaux records a case of carcinoma of the left vocal cord,[1] which is of especial interest as bearing on the case of the late Emperor Frederick. The patient, fifty-three years of age, consulted Dr. Lichtwitz in November, 1889, for loss of voice, which had been almost absolute since the previous August, and from which he had suffered at times during the past two or three years. His health had been previously good, and there was no suspicion of syphilis, whilst the aphonia was the only symptom present. Laryngoscopical examination showed a smooth, fusiform, yellowish-grey swelling occupying the anterior two-thirds of the left vocal cord, which was congested posteriorly. The movements of the cord were impaired. A portion of the growth, which was suspected to be of malignant nature,

[1] Ext. des Annales des Maladies du l'Oreille et du Larynx.

Digitized by Google

was removed, and pronounced by M. Ferre to be so. But as it was thought desirable to get a further opinion, another portion was excised, and the sections sent to Professor Waldeyer of Berlin. He reported that they contained several horny bodies and papillary excrescences, but reserved an opinion as to their cancerous nature, until it had been determined whether the growth was circumscribed or diffuse. He said that the preparations were very similar to those examined by Virchow in the Emperor's case, and remarked that in that case it was the subsequent examination of the sputa and the clinical course which convinced Drs. Gerhardt and Bergmann of its malignant nature. In the present case, antisyphilitic treatment proving of no avail, further portions were examined and extirpation was decided on. Waldeyer reported on these later specimens that the growth was obviously papillary, and that if not already carcinomatous it would probably become so. M. Demons undertook the operation, and removed the growth by splitting the larynx, a preliminary tracheotomy having been performed some days previously. The operation took place on Feb. 22nd, and proved to be very difficult and tedious, since, in spite of the tampon, much material was drawn into the bronchi. The growth was very thoroughly removed and the exposed parts cauterised, but the patient succumbed to broncho-pneumonia five days later. The carcinomatous nature of the affection was determined without question, and it was found that the cartilage was becoming infiltrated. Professor Waldeyer reported that there was great proliferation of the epithelium and an unusual degree of laminated tissue. He therefore regarded the growth as an example of scirrhus, whereas that of the Emperor Frederick was medullary. Dr. Lichtwitz, in his comments on the case, remarks on the paucity of symptoms, and cites with approval the conclusions of Dr. Semon, not to wait for absolute histological proof from extirpated fragments before excising, if the clinical course of the growth is that of malignant disease.

THE ASYLUMS BOARD AND DR. COLLIE.

A RESOLUTION has been passed by the General Purposes Committee—which is a committee of the whole Board—recommending a pension of $\frac{2}{3}$ths of £600 to Dr. Collie, who has resigned his position as medical superintendent of that hospital. The matter will be finally settled by the Board on Jan. 9th, 1892. We trust that the result of the decision will be the award of a liberal pension to Dr. Collie—one adequate to the eminent services which he has rendered in connexion with the duties of the office which he has just vacated, as well as in view of his valuable contributions to the literature of infectious diseases.

CASES IN VESICAL AND URETHRAL SURGERY IN NEW YORK.

THE *New York Medical Journal* contains an interesting paper, read by Dr. Fred. S. Dennis, on some cases of vesical surgery. One of these was that of a man who, after slipping from a scaffold, fell astride a staging horse and ruptured his urethra, giving rise to extravasation of urine and deep perineal abscess. On admission to the hospital, in a very weak and anæmic state, there was a large opening in the perineum, in which the two ends of the ruptured urethra could be seen two inches apart. There was also acute cystitis. During the few days following admission there were several severe hæmorrhages from the wound, rendering the patient pulseless, and requiring hypodermic injections of brandy and digitalis. On Nov. 5th, after eleven such hæmorrhages, his condition was so alarming as to induce Dr. Dennis to tie the internal pubic artery. This effectually stopped the hæmorrhages. The wound in the perineum soon began to granulate. A catheter passed through the penile portion and then into the proximal end of the urethra was left in the bladder. It was ere long covered with granulations, the two inches of urethra were made up, and the patient passed most of his urine through the penis. In less than six months the urethra was quite healed. Case 4, reported by Dr. Dennis, is that of a supra-pubic lithotomy by which a large stone was removed without the slightest difficulty, weighing 1360 grammes (about forty-four ounces), measuring seven inches in circumference and two inches and a half in diameter. The patient was twenty-four years old, and had had hæmorrhage and other symptoms of stone for nineteen years. The urine contained a great deal of pus, the patient was exceedingly pale, and he weighed less than 100 pounds. He recovered perfectly and gained thirty-five pounds in weight. Case 9 was one of hæmorrhagic cystitis occurring as a complication of typhoid fever, the formation of a calculus with a blood-clot as a nucleus, and the extrusion of a complete cast of the interior of the bladder.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Dr. H. Thierfelder of Strasburg has been recognised as *privat docent* in Medical Chemistry.

Harvard.—Dr. H. C. Ernst has been appointed Assistant Professor of Bacteriology.

Kazan.—Dr. Malinovski of Kieff has been appointed to the chair of Operative Surgery.

Prague (Bohemian University).—Dr. Mischel has been promoted to an Extraordinary Professorship.

St. Petersburg (Military Medical Academy).—Drs. Batuyeff and Fabitski have been recognised as *privat docenten* in Anatomy and Clinical Medicine.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Otto von Gärtner, formerly Body Physician to the King of Wurtemburg, on Dec. 9th, at Stuttgart, in his seventieth year. He was the first surgical director of the Catherine Hospital, and was not only a good ophthalmologist, but enjoyed a large medical practice as well.—Dr. Jean Servais Stas, Professor of Chemistry in the Brussels Military Academy, at the age of seventy-eight. He was a medical man, and contributed considerably to the application of chemistry to forensic medicine and to the investigation of animal substances, such as the amniotic fluid. Indeed, his name is known to every student of elementary organic chemistry.—Dr. G. Kordi, ordinator of the Gynæcological Clinic of the St. Petersburg Medical Academy.—Constantine Leonteiff, who, though a medical man, is known chiefly by his writings on ethnography and non-medical subjects. He was at one period of his life in the Russian diplomatic service, being stationed in Turkey and Greece. He was then appointed censor of the press at Moscow, and some years ago entered a Russian monastery as a monk.

IT may be well to remind our readers that the five years' curriculum will apply to all candidates for the licence of the Royal College of Physicians and for the diploma of member of the Royal College of Surgeons of England who register as medical students after Jan. 1st, 1892. The revised regulations are not yet ready for issue, but it is probable that they will be published before the end of January.

PROFESSOR CELLI of Rome, whose "Reminiscences of an Italian at the International Congress of Hygiene" were lately given in THE LANCET, has just delivered (Dec. 28th) an address in that city on "Woman's Place in Social Hygiene." Her Majesty the Queen of Italy presided.

Digitized by Google

IT was reported in several of the German medical journals last week that Professor Ph. Schech of Munich was dead. This, fortunately, is not the case, though he was seized, while performing a very long and troublesome laryngeal operation, with sudden spasm of the glottis, which was followed by a tetanic condition, from which, however, he is recovering.

AT the meeting of the Election Committee of the Middlesex Hospital on Wednesday last Dr. W. Essex Wynter was elected Assistant Physician, in succession to Dr. Kingston Fowler, who has been appointed fourth Physician. Dr. Wynter has for the past three years been medical registrar to the hospital, and is an *alumnus* of its school.

THE death is announced of Dr. Richet, Professor at the Faculty of Medicine and surgeon at the Hôtel Dieu, at the age of seventy-one.

MR. ANTHONY A. BOWLBY, F.R.C.S., has been appointed Assistant Surgeon to St. Bartholomew's Hospital.

SIR WILLIAM TURNER has been appointed a Deputy-Lieutenant of Edinburgh.

Pharmacology and Therapeutics.

STRONTIUM IN PARENCHYMATOUS NEPHRITIS.

M. Constantine Paul, writing in *Les Nouveaux Remèdes* on the treatment of Bright's disease by strontium, remarks that Carlsbad water contains a small quantity of the carbonate of strontium, this being practically the only difference, chemically speaking, between the true Carlsbad water and what has been called French Carlsbad—that is to say, the water of Miers in the department of Lot. Professor Sée has made some observations as to the value of strontium in place of sodium; but M. Paul, arguing from its place in the electro-negative series between lithium and calcium, thought it might more probably be found suitable as a substitute for lithium. The salt he generally employed was the lactate, and of this he has during the last few months prescribed more than a couple of pounds in addition to smaller quantities of the bromide and nitrate. According to some physiological researches recently published by M. Laborde, the salts of strontium are innocuous, thus contrasting with those of barium, which are highly poisonous, and with those of potassium, which are not well borne in large quantity. Strontium salts are not diuretic, and they have the property of diminishing the albumen in epithelial and parenchymatous nephritis, though they do not altogether stop its formation. If the drug is discontinued prematurely the albumen increases again. A large number of cases having been treated with strontium, M. Paul is now in a position to give the following general results. It is useful in parenchymatous nephritis, whether of rheumatic, scrofulous, or gouty origin; also in the albuminuria of pregnant and parturient women. He is not able to say as yet whether it is suitable in scarlatinal albuminuria or in the albuminuria of other infectious diseases, or in that depending on syphilis, or in cardiac cases. It has, however, shown itself valueless in interstitial nephritis, and also in the albuminuria of phthisis. As a rule, the diminution of the albumen is followed by a marked amelioration in other symptoms, and the patient improves considerably. In order that the treatment may succeed it is important that it should be commenced before the period of urinary insufficiency and uræmia has arrived. Pyrexia, however, even when of a high degree, does not prevent the lactate of strontium from exerting its beneficial action in parenchymatous nephritis. It has been suggested that bromide of strontium might be found useful in epilepsy; but of this M. Paul has only had the experience of a single case, where, indeed, it appeared to succeed in a remarkable manner after bromide of potassium had been given in large doses without effect. The daily quantity of bromide of strontium ordered in this case was ninety grains, and this was continued for two months. In the nephritic cases the dose of the lactate per diem was from 120 to 150 grains, and in no case was it badly borne.

CANTHARIDATES IN TUBERCULOSIS.

In a recent number of *Merck's Bulletin* numerous investigations of the efficacy of cantharidates are reported, the cases varying from lupus, tuberculous ulcers, and granular lids to laryngeal and pulmonary tuberculosis. Opinions differ with regard to the pain produced at the point of injection; according to one observer all the patients complained of intense pain. With very few exceptions there was no rise of temperature or other sign of general reaction. None of the patients ever complained of any urinary difficulty or symptoms referable to irritation of the urinary organs. The beneficial results in cases of lupus are said to have been very striking; the cases of granular lids were markedly improved; most of the cases of laryngeal phthisis underwent considerable improvement, but in two cases in which fever was present before the treatment was begun the injections seemed to have no particular effect on the fever or on pulmonary symptoms On the other hand, it is stated that it has no effect on the tuberculous processes in the lungs, that it neither sets up nor reduces fever, and that it has no effect on the number or shape of the bacilli. Professor L. Tümas concludes that on the whole the cantharidate treatment is decidedly beneficial in some cases, and hence deserves a further trial. Its chief advantages are that the medicament can be prepared by everybody, that it admits of precise dosage, that it does not give rise to any serious complications, and that it can be safely applied to out-patients, as it does not involve any change in the patient's usual mode of life.

CAMPHORIC ACID IN PHTHISIS AND IN CYSTITIS.

Camphoric acid has been employed in cystitis, and as an intestinal disinfectant, by Fürbringer; it has also been used with success in the treatment of the night sweats of phthisis. More recently Bohland has been employing this drug, of which he gives one gramme in a wafer at nine or ten o'clock at night. The dose may be increased to two grammes, or even to three grammes if necessary; for some patients who only begin to perspire towards the morning it may be well to administer the camphoric acid at two or three o'clock in the morning. The results he obtained were satisfactory in about 80 per cent. of the cases. Camphorate of soda appears to have an action somewhat inferior to that of camphoric acid. In two cases the acid, given in the dose of three grammes in three doses, arrested phthisical diarrhœa which had resisted other methods of treatment. In cystitis when the urine is ammoniacal and alkaline it can be speedily cleared and rendered acid by three grammes of camphoric acid in the day, given in three doses. The acid is eliminated with the urine from two to five hours after its administration. Urine thus impregnated with camphoric acid may be kept several days without undergoing putrefaction.

A NEW METHOD OF TREATING DIPHTHERIA.

Dr. Charles Smith of Casterton, Australia, has recently given his experience of a new method of treating diphtheria. It has the advantage of not necessitating the stoppage of other methods of treatment. Briefly stated, the treatment consists in the continuous inhalation of a vapour composed of a mixture of carbolic acid, eucalyptus oil and turpentine, together with the administration, in ordinary doses, of tincture of digitalis, tincture of belladonna, and aromatic spirit of ammonia. The only novelty claimed by Dr. Smith is the continuous employment of the inhalation, together with the method of applying it. The ingredients are mixed in the following proportions:—Carbolic acid 1, eucalyptus oil 1, turpentine 8. Sometimes, however, he has used them in the strengths of 1-1-4. In the mixture two cloths, about a foot square, are soaked; one is placed close to the face, the other on the pillow near the head; one or two others are hung about round the cot. It is important that none of the cloths should be allowed to touch the face. Brief notes of seventeen cases are given.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—Notice has been issued that a meeting of the members will be held at 3, Bolt-court, Fleet-street, on Tuesday Jan. 12th, at 4 P.M.

REPORT OF

The Lancet Sanitary Commission

ON THE

VENTILATION OF THEATRES AND PLACES OF PUBLIC ASSEMBLY.

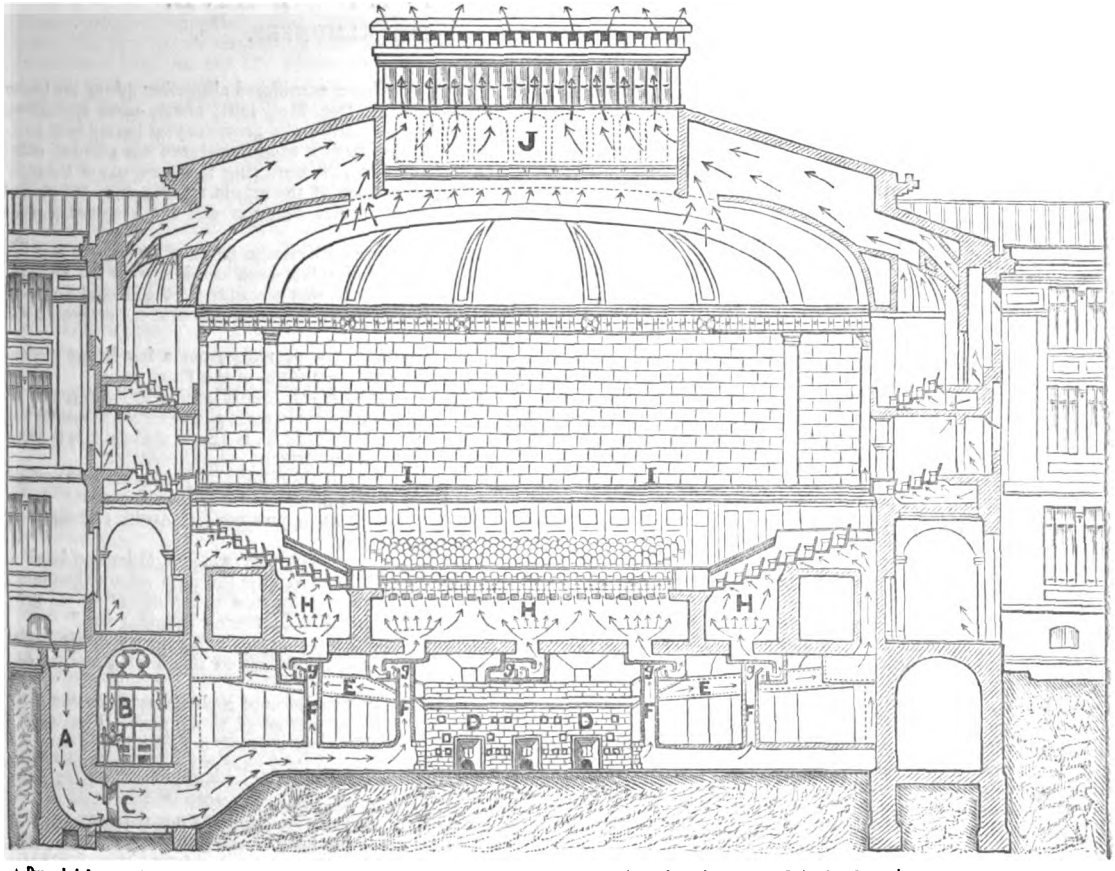
PART II.—THE PARIS SORBONNE.

WE will now describe the ventilation of the great amphitheatre of the Paris Sorbonne, which contains 3000 seats, and is the most recent application of the principles we have attempted to explain. We have already remarked that the Paris Sorbonne was the latest application of the principles of ventilation so successfully employed at the Vienna Opera House. Of course we allude to the new Sorbonne, the magnificent edifice that abuts on the Rue des Ecoles, which was inaugurated in 1889, but which, nevertheless, has not yet come fully into use. Within this structure there is an immense amphitheatre, where all the great ceremonies connected with the Paris University take place. Here the problem of warming and ventilating is as difficult as in a theatre, for 3000 seats have to be provided; while that of the form of structure is even more difficult, for the seats should be all equally good. The building, however, differs from a theatre inasmuch as there is a platform instead of a stage. The form adopted is that of most Parliament houses—namely, the semicircle, with a platform instead of the tribune. The president's seat is of course in the centre of the platform, facing the half-circle. The pit or floor is about the size of the platform—namely, only half the width of the amphitheatre. On each side and all round rise tiers of seats, while on the floors above there are two galleries. Even the sectional drawing, which we give, will at least partially show that the seats are all equally good and command an equal view of the platform. It will be observed how under every seat there is an air inlet. In fact, the seats in the galleries, as in the body of the hall, are all suspended over air chambers, and these air chambers form the third of the series—namely, the mixing chambers similar to what we have seen at the Vienna theatre. Yet the ventilation only resembles that of the Vienna Opera House in general principle; there is a difference in detail. The air is propelled into the amphitheatre by the force of three fans that stand side by side in the inlet passages or air shafts. A portion of the air is conducted into a furnace, where it is warmed, the other portion travels upwards towards the mixing room. The two shafts, however, meet together just below the floor of the mixing room. Here a very simple apparatus enables the attendants to open more or less widely the door or valve of the cold air shaft. The wider it is opened the greater the current of cold air as compared with that of the warmed air, and thus by moving these valves the temperature of the mixing chamber is easily regulated.

The three fans propel each 20,000 cubic metres of air per hour. This is, therefore, a total of 60,000 cubic metres. But if they were made to revolve with exceptional velocity the supply of air could be raised to 72,000 cubic metres per hour. These fans are unusually large in diameter, more than six feet, and they only make about 150 revolutions in the minute. They were designed especially to produce a plentiful but slow current of air. When a shaft is very long and force is required to send the air forward a great distance, as in the ventilation of coal mines, then the Ser ventilator would, with its great centrifugal force, render better service. But at the Sorbonne the object was the reverse—namely, that of moving a large volume of air over a wide space at a slow rate. The power is provided by a gas motor engine of 15 horse-power. As the air enters the underground passages it can be moistened in summer by a spray of water. This spray is produced in the same manner as that which exists at the House of Commons, whence the idea was derived.

When tenders were invited for the ventilation of the Sorbonne, the condition stipulated was that each person should be supplied with 20 cubic metres of air per hour. A well-known firm of French sanitary engineers, Messrs. Geneste and Herscher, were successful in the competition that ensued, and we have seen that the screw fans which they provided, by propelling 60,000 cubic metres of air per hour, supply precisely the 20 cubic metres required for each of the 3000 persons who can be seated in the amphitheatre. But with mechanical force it is easy enough to give any amount of air; the difficulty is to ensure its even distribution, and this in so slow and gradual a manner as to be imperceptible. To moderate the current, the air inlets, which are cut out in the floor under every seat, are covered over with two perforated iron plates, placed about an inch one above the other. The perforations in the plates are very small namely, four millimetres in diameter. These iron perforated plates measure about 8 in. by 14 in., but the total useful surface for air inlet amounts throughout the whole amphitheatre to 80 metres square. The rapidity at which the air enters is equal to 25 centimetres per second. The outlets measure in all 45 metres square; they are situated in the roof of the hall and under the galleries. Here the air passes out at the rate of 50 centimetres per second. Gas-burners help to draw upwards the vitiated air till it reaches the final outlet shaft, which measures 14 metres square; and in this shaft the air travels at the rate of 1 metre 20 centimetres per second. It has not been found necessary to place an exhaust fan in this outlet shaft; the air, being warm and forced in from below, naturally goes upwards.

Thus we find realised at the Sorbonne what had already been done at the Vienna Opera House. In the screw fans and the 15 horse-power engine are the mechanical means of providing with mathematical exactitude the amount of air required. Then there is the large mixing chamber, where, by means of nicely adjusted valves, the attendants can regulate the inlet of hot air and of cold air so as to make an atmosphere which they generally warm to 65° F. The inlets are so numerous and large that the air can only travel through them slowly, and, being subdivided by the minute perforations in the iron plates placed over the inlets, occasions no draught. All this, we repeat, is a copy of what we have seen at Vienna; but Messrs. Geneste and Herscher were determined to go a step further, and attempt to realise for the Sorbonne M. Émile Trélat's highest conception of good ventilation.



M. Trélat's ideal of well-being is a fine autumnal day, when the air is cold and crisp, but the rays of the sun are still warm. The colder the air, the greater the internal oxidation in breathing, and therefore the greater the internal warmth. If while breathing cold air the body can be preserved from external cold by the radiation of heat from the sun or other sources, then the most healthy and the most enjoyable state of physical existence results. We know that the atmosphere takes up little or none of the heat that passes through it by radiation. To realise this ideal the walls surrounding the amphitheatre are hollowed, and inside there is a canalisation by which heat can be imparted to the substance of which they are built. Also the flat wall facing the amphitheatre, by reason of its size and the coldness of the stones with which it is built, would chill the air in the body of the hall and determine a down current. This would strike the heads of the professors sitting on the platform. To obviate such a danger, at a height of about ten feet above the platform, and for the whole length of the wall, there is an emission of especially heated air, which counteracts the down current and the chill created by this broad surface of cold wall. Thus the cold produced by the material of the building itself is neutralised. This is not all. Though, as already explained, there are ample means of providing warmed air throughout the whole of the amphitheatre, it can also be ventilated with cold external air in the midst of radiated heat. To secure this imitation of M. Trélat's ideal autumnal, cold, bright, sunny day, the air-mixing chambers of the amphitheatre are closed about an hour before the public are admitted. The batteries in the heating furnace are raised to about 300° to 400° C. The air passing over these very hot warming batteries is allowed to escape up all the hot air shafts built inside the walls of the amphitheatre. It enters the amphitheatre by the openings such as that situated ten feet above the platform, and travels upwards along the cold surface of the walls, which are soon warmed. As this is proceeding the air in the mixing chamber, by its proximity with the furnace that is in the chamber below, becomes slightly warmed. It therefore expands and travels

Digitized by Google

upwards through the multitudinous openings into the body of the hall. In a very short time the temperature of the whole amphitheatre is raised to about 160° F. The place is therefore absolutely untenantable. The walls, the furniture, everything in the amphitheatre is thoroughly heated, and soon absorbs and husbands a large stock of caloric. Then about a quarter of an hour before the public are admitted all the hot-air supply is cut off, and the warming of the amphitheatre entirely stopped. The air-propelling screw fans are now set in motion. They pump into the amphitheatre pure cold air from the street. The overheated air is soon driven out, and by the time the public enter they find in the amphitheatre exactly similar air to that they were breathing in the street. This air has not been warmed or mixed with warmed air in any way; it is a pure and, so to speak, an unadulterated out-of-door atmosphere. But through this cold air is radiated the heat given off by the hot walls and furniture of the amphitheatre. Also the cold incoming air as it strikes the hot walls is warmed. It therefore becomes lighter, expands, and travels upwards towards the outlets in the ceiling. If, on the contrary, as is usually the case, the walls were cold and the incoming air was warmed, then the air on striking the walls would be cooled, would condense, would become heavier, and therefore would fall as a cold draught on the heads of the people below. The walls of the amphitheatre retain their heat for a few hours; that is long enough for the ordinary meetings held in this magnificent assembly hall. Thus the Sorbonne amphitheatre can be warmed and ventilated as is the Vienna Opera House, with a carefully prepared mixture of hot and cold air; it may be ventilated with pure cold outside air, and warmed by radiation from its heated walls, or the two systems may be combined if desired.

There is something especially fitting in the fact that this, the great centre, where honours and rewards are distributed to those who have distinguished themselves in learning and science, should in itself be an example of what science can achieve for the comfort and health of the audiences privileged to assist at any of the meetings held in this amphitheatre. At the Sorbonne will be crowned the laureates of the Paris University, but crowns should also be reserved for those who have made its amphitheatre an example to the world of what can be done to secure the due observation of Nature's laws by continuing the provision of pure air, even when 3000 persons have to assemble under one roof and in one single hall.

THE NEW SORBONNE, PARIS.

A, Pure air inlet. B, Engine house. C, Inlet ventilating fan. D, Furnace for warming the air. E E, Hot air shaft. F F F F, Cold air shafts. g g g g, Valve regulating amount of cold air, which here joins the hot air shaft. H H H, Hot and cold air mixing chambers. I I, Hot air pipe to counteract cold down draught caused by the wall. J, Burners above glass reflecting roof, serving to light the amphitheatre and draw off the foul air.

NEW INFIRMARY BUILDINGS, ST. OLAVE'S UNION.—Recently the opening ceremony took place of the new pavilions at the infirmary, Lower-road, Rotherhithe. They have been erected by the guardians of the poor of the St. Olave's Union, and will provide room for 280 beds, raising the total accommodation to 650 beds. The outlay has amounted to about £36,000.

BROWN *v.* DUKES AND CARPENTER.

AT a special meeting of the members of the Croydon Medical Reading Society, held Dec. 22nd, at the house of Mr. Richardson, the following resolutions were passed unanimously:—1. That steps be taken to raise a fund towards defraying the expenses incurred by Drs. Duke and Carpenter in defending the action Brown *versus* Dukes and Another." (2) That Dr. Coles, George-street, Croydon, be requested to act as treasurer of the fund, and that Mr. Richardson, 87, London-road, West Croydon, act as secretary. (3) That the secretary be requested to send circulars to all the members of the South-Eastern Branches of the British Medical Association, and other medical men in the district. (4) That the preliminary expenses of soliciting subscriptions be borne by the funds of the Society. (5) That the Editors of THE LANCET and *British Medical Journal* be asked to kindly acknowledge the subscriptions in their columns. The following sums have been promised:—

Dr. Adams	.. ..	£2	2	0	Dr. Morton	£2	2	0
Mr. Horsley	.. ..	2	2	0	Dr. Coles	2	2	0
Mr. Richardson	.. ..	2	2	0	Dr. Duncan	2	2	0
Mr. Wray	.. .. ..	2	2	0	Dr. Philpot	2	2	0
Dr. Barnes	.. .. ..	2	2	0	Dr. Rosser	2	2	0

*** It will be remembered that we have already opened a subscription list on behalf of the defendants in this action, and that a preliminary list of subscribers was published in our issue of Dec. 19th. We shall, however, be pleased to coöperate with the Croydon Society to hand over to Dr. Coles, the treasurer, the sum we have received, and to acknowledge further subscriptions.—ED. L.

THE LANCET RELIEF FUND.

THIRD ANNUAL REPORT OF THE ALMONERS.

THE LANCET Relief Fund, which has for its Almoners the President of the Royal College of Physicians (Sir ANDREW CLARK, Bart., F.R.S.), the President of the Royal College of Surgeons (Mr. THOMAS BRYANT), the President of the General Medical Council (Sir RICHARD QUAIN, Bart., F.R.S.), Mr. THOMAS WAKLEY, F.R.C.S., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D. Camb., F.R.C.P., as Honorary Auditor, came into operation on the 1st of February, 1889.

In presenting the third annual report, the Almoners think it well again to direct attention to the objects for which the Fund was established.

For the sustentation of the Fund the sum of at least £300 will be provided every January by the Proprietors of THE LANCET, and administered free of cost, for the purpose of affording immediate pecuniary assistance to registrable medical practitioners, or to the widows or orphans of members of the profession in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

When the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established; and, as a result, the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. Attention was called to this fact in THE LANCET of Feb. 16th, 1889, in the following words:—

"We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress, the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registrable medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected exigency which is not likely to recur, have pressing need of immediate and temporary pecuniary relief," and who, it may once more be pointed out, are likely to be permanently benefited thereby.

The balance in hand at the end of 1890 amounted to the sum of £125 19*s.* 6*d.* On January 1st, 1891, the Proprietors of THE LANCET placed to the credit of the Fund the sum of £300. During the course of the year repayments to the amount of £33 16*s.* 6*d.* have been made. The sum of £289 2*s.* has been granted in relief either by way of loan or of gift, leaving a balance of £170 14*s.*

There have been considered altogether during the twelve months ending Dec. 31st, 1891, twenty-seven applications for relief (the number the previous year having been forty-five). In twenty-two cases assistance was afforded, either as a loan or as a gift, according to the request of the applicant, the amounts of the grants ranging from two guineas (given on a special occasion and for a special purpose) to £25.

In some cases of extreme urgency, as was the case last year, an application has been considered by the Almoners, a grant sanctioned, and a cheque for the amount forwarded to the applicant on the same day that the application was received.

The following are extracts from a few letters received from some of the recipients of the Fund:—

CASE 92.—"Will you kindly express to the Almoners his heartfelt thanks for their great consideration in sending him a gift of £10, for which he is deeply grateful. It is such a comfort to us in our present painful position."

CASE 95.—"I am in receipt of your letter with enclosed cheque for £25, for which I am deeply grateful. It has come to me most opportunely. Again expressing my abiding gratitude."

CASE 99.—"I cannot find words sufficient on behalf of myself and family to express the deep sense of gratitude I feel for your liberal response to my appeal for aid in my present distress. Again sincerely thanking you."

CASE 100.—"I beg to thank you for so kindly lending me £25, which enables me to tide over a pressing difficulty."

CASE 112.—"Your prompt reply to my application to the Almoners was truly a relief to my mind. I was afraid I should lose a chance of earning a livelihood for want of a few pounds. ..... Pray express, on my behalf, more adequately than I can, my appreciation of the kindness shown to me by the Almoners."

CASE 113.—"I beg to sincerely thank the Almoners for their very kind response to my appeal, and to assure them that I shall ever feel grateful to them for the same. I have every reason to hope that the advance made will enable me to hold my ground. Assuring you how deeply I feel your kindness."

CASE 114.—"I am instructed by Dr. —— to express his sincere gratitude for the donation enclosed in your letter of ——. It reached him just in time, as he was totally destitute and actually starving."

CASE 98.—Extract from a letter received on final repayment of an advance: "I can only say that I am very much obliged indeed for the loan, which has been of the greatest use to me."

A resolution was passed at the meeting of the Almoners, expressing their deep regret at the loss the Fund had sustained by the death of Professor Marshall, who was one of the original Almoners of the Fund.

Mr. Edward Davies has been appointed Secretary to the Fund.

(Signed)

I find by the Banker's Book that the actual balance on Jan. 1st, 1891, to the credit of the Fund was £125 19*s.* 6*d.*, to which the sum of £300 was added by the Proprietors of THE LANCET on the same day.

The balance at the Banker's at the present date is the sum of £170 14*s.* I have also checked the receipts for disbursements, and find the above account strictly accurate.

December 24th, 1891. HENRY A. PITMAN, Hon. Auditor.

THE MEDICAL SOCIETIES.

WE much regret that, owing to an unfortunate delay in the post last week, we were compelled to hold over our annual review of the work of the Medical Societies during the past year. In the accompanying short glimpse of the work that has been accomplished we have followed our usual custom, and have selected a few only of the many prominent communications for notice, it being quite impossible to deal with even a majority of them in at all an adequate manner. We may preface our remarks, however, with the assertion that the material produced before the Societies during the past twelve months has been equal in value to that of any previous year. All the old Societies continue to increase in their numbers and to flourish financially, while the last month of the year has given birth to another, which has been christened "The North London Medical and Chirurgical Society." Its chosen place of meeting is the Great Northern Central Hospital, and a considerable accession of members has already justified it in looking forward with confidence to a prosperous and useful career.

We will commence our retrospect with the *Medical Society of London*. The subject of the treatment of chronic disease of the uterine appendages was introduced by Dr. William Duncan in a paper giving notes of thirty consecutive cases treated by abdominal section, and Mr. Alban Doran at the same meeting gave a brief historical view of the whole subject. Dr. Douglas Powell inaugurated a discussion on the subject of angina pectoris, which he held was not such a simple malady as had been thought, and which he classified, according to the symptoms, into four subgroups. Mr. Edmund Owen referred to a case in which he had amputated both breasts simultaneously for cancer, and held that, contrary to the teaching of text-books, bilateral disease should not be considered a bar to operation. An interesting series of cases illustrative of hepatic surgery was communicated by Mr. Knowsley Thornton. Surgeon-Major Keegan of Indore brought forward the results of his experience as to litholapaxy in children, and he tabulated and commented upon the 125 operations which he had performed in males below fifteen years of age. Dr. B. W. Richardson pointed out the various methods of administration of peroxide of hydrogen. Dr. De Havilland Hall read a paper on chronic atrophic rhinitis, discussing fully its etiology and treatment. Mr. Buckston Browne emphasised the importance of the post-prostatic or trigonal pouch in the surgery of vesical calculus, illustrating his remarks by several cases. Dr. G. A. Heron gave his experience of the use of Koch's remedy in lupus vulgaris and in tuberculosis of the lung. Mr. Whitehead brought before the Society a list of 104 cases of entire excision of the tongue carried out by the method he had recommended. Mr. Mansell Moullin advocated the treatment of compound fractures into joints by corrosive sublimate baths. Professor Bahadhadji gave his experience of the treatment of dysentery by simple therapeutic measures. Mr. H. Allingham read a paper on fifty cases of left inguinal colotomy, and remarked on their points of special interest. Dr. Julius Althaus dealt with the pathology of influenza from its neurotic aspect, and Dr. G. H. Savage gave his views on the relationship of this disease to the neuroses. Dr. Burney Yeo enumerated what he considered to be the conditions of cure in consumption. Mr. Richard Davy gave his experience of amputation at the hip-joint, illustrated by ten cases. Dr. Thomas Savill furnished a detailed description of the epidemic skin disease at Paddington Infirmary, and at the last meeting Dr. Ord read a thoughtful paper on the occurrence of cardiac symptoms in conjunction with gastric ulcer.

At the *Royal Medical and Chirurgical Society* cases illustrative of the advance which has been made in dealing surgically with calculous affections of the kidneys were described by Mr. Lucas, Mr. Godlee, and Mr. Turner. Dr. Pye-Smith communicated a paper on the therapeutic value of venesection, in which this practice was held to be useful in meeting certain indications of pathological states, especially in cyanosis from obstruction, the intense pain of aneurysm, and in uræmic and prolonged epileptic convulsions. Sir George Humphry, dealing with the subject of macrodactyly and some other forms of congenital overgrowth in their relation to tumours, held that the process in both was analogous, both being instances of insubordination to the laws of development and growth. Mr. Barwell advocated a method of treatment which he called rachilysis for straightening spinal curves. The curious condition

Digitized by Google

known as idio-glossia was illustrated by papers introduced by Dr. Hale White, Mr. Golding-Bird, and Dr. Frederic Taylor. Mr. Lockwood dealt with the subject of the treatment of strangulated hernia when the intestine was gangrenous or ulcerated, and he concluded in favour of primary resection and suture. Mr. John H. Hutchinson discussed the possibility of the poison of measles acting as a cause of endocarditis, but he seemed to think that a rheumatic taint was at the bottom of the cases he quoted. A very suggestive paper from the pen of Mr. Arbuthnot Lane dealt with the subject of chronic traumatic arthritis, which he differentiated from rheumatoid and rheumatic arthritis respectively. Mr. Watson Cheyne gave the results of his investigations into the value of tuberculin in the treatment of surgical tubercular diseases. Mr. Bowlby read a paper on thirteen cases of Paget's disease of the nipple, and he concluded that there was no evidence to support the view that the growths were caused by psorosperms. Dr. Délepine and Mr. Dent gave the result of their researches as to the changes observed in healthy arteries and in tendon ligatures during the first four weeks after ligation. Dr. George Thin and Dr. Wethered communicated a paper on the symptoms and pathology of a case of acute inflammation of the mucous membrane of the ileum from climatic causes. Mr. Raymond Johnson and Dr. G. Murray used a case of limited lesion of certain spinal nerve roots by secondary carcinoma to demonstrate the source of the nerve supply of certain muscles. Dr. A. Haig held that uric acid was an important cause of high arterial tension. Cases illustrative of the infection of the human subject by actinomycosis were brought forward by Dr. W. H. Ransom, Dr. W. B. Ransom, and Mr. A. R. Anderson. Mr. Lawson Tait drew attention to the occurrence of pleural effusion in association with disease of the abdomen. Mr. D'Arcy Power produced an analysis of sixty-three cases of ununited fracture occurring in the long bones of children. He believed that these lesions were more frequent than they formerly were.

At the *Pathological Society* many subjects of great interest were discussed, and we are only able to select a very few of them for remark. Sir Hugh Beevor read a note on media for the cultivation of the tubercle bacillus, demonstrating the wide range of temperature at which these organisms would grow. Dr. S. M. Copeman showed specimens of urine containing hæmato-porphyrin, from cases which the author believed were allied to pernicious anæmia. In connexion with the latter disease Dr. Wm. Hunter had isolated from the urine certain putrefactive alkaloids which he believed were causative of destructive changes in the blood and of inflammatory lesions in the coats of the stomach. Dr. Samuel West described a case of chronic general nodular tuberculosis in which the lesions were of a kind common to some animals. An important communication was made by Professor Crookshank on the morphology, cultivation, and toxic products of the tubercle bacillus. Dr. Job Collins brought forward a case of asymmetrical kidney from atrophy of its fellow, and dwelt on the importance of recognising the occurrence of these cases when nephrectomy was contemplated. Mr. Stephen Paget showed specimens of imperforate anus, and pointed out the frequency with which other malformations were associated with these cases. Mr. Bland Sutton brought forward several specimens illustrative of comparative pathology. He showed a sheep's head with a cervical auricle, and a tooth which had been removed from a persistent second bronchial cleft in a horse. He likewise described an "implantation cyst" removed from an ox. Mr. Howard Marsh exhibited some loose bodies which had come from a knee excised for tubercular disease; and Mr. Bruce Clarke, at the same meeting, showed a piece of cartilage which had been chipped off the patella as the result of an accident. Dr. Galloway read a paper on a well-marked specimen of syringomyelia, and described its minute anatomy. An interesting case of tuberculosis of a tendon-sheath was brought forward by Mr. E. C. Stabb. Mr. Sydney Jones exhibited a specimen of perforation of the gall-bladder from calculi. Mr. William Anderson brought forward a case of fæcal fistula at the umbilicus associated with imperfect development of the large intestine, which terminated in a blind extremity six inches from the ileo cæcal valve. Dr. Albert Wilson gave a paper on the micro-organisms of diphtheria, with experimental results in animals. Mr. W. H. Battle showed specimens of epiphysitis obtained from long bones in infants under one year of age with disease at one or both articular ends. Dr. Voelcker showed specimens illustrating the involvement of the lung by caseous bronchial glands in children; the pulmonary changes in these cases he regarded as secondary. Dr. Délepine showed some cultivations of psorosperms, and stated that he had obtained typical examples from the viscera and skin in various diseases. Messrs. Shattock and Ballance related the negative results they had obtained with psorospermial inoculation of animals. Mr. Clutton exhibited a patient with a median hare-lip. Mr. Charters Symonds exhibited microscopical sections of the callus of simple fractures to demonstrate the process of ossification through cartilage. Mr. Shattock communicated the results of a research on the action of proteus vulgaris and of pyococci on urine. Mr. Bland Sutton accounted for the existence of the mandibular tubercle and cicatrices, drawing his illustrations from both human and comparative sources. Dr. Walter Sibley described the results of his experiments in inoculating tubercle into snakes. A careful description of a case of xanthoma diabeticorum was furnished by Mr. Malcolm Morris and Mr. Clarke. Dr. E. T. Wynne described a series of specimens illustrative of the origin of cysts in pachymeningitis hæmorrhagica; he denied the inflammatory origin of this affection. Dr. Herbert Larder described fully the lesions in a case of leprosy that had been under his care; he regarded the tuberculated and anæsthetic varieties of the disease as essentially similar.

The subject of intussusception was brought before the *Clinical Society* by Dr. Whipham, Mr. Turner, and Mr. Lockwood. Dr. Sidney Phillips dealt with the subject of typhoid fever, fatal at a late period, without intestinal ulceration, and he discussed the clinical signs, which were indicative of the latter complication. Dr. Hale White and Mr. Arbuthnot Lane described a case of stricture of the pylorus following upon hydrochloric acid poisoning, in which a modified Loreta's operation was performed. Cases of excision of the vermiform appendix were brought forward by Mr. Herbert Allingham, Mr. Sutton, and Mr. Andrew Clark, and were followed by an animated debate, in which the success of medical treatment in the early stages of these cases was insisted on. Dr. Gowers read an account of a case of acute atrophic paralysis in which there was a primary multiple neuritis. Mr. Pearce Gould described a peculiar case of symmetrical gangrene of the feet from obliterating disease and thrombosis of the arteries and veins, which he classed with the rare cases of primary arteritis obliterans. Mr. A. T. Norton communicated a case of popliteal aneurysm in a boy of seventeen caused by a femoral exostosis. Cases illustrative of the value of nephrolithotomy in the treatment of calculous nephritis were related by Messrs. Turner, Jacobson, and Pollard. The subject of gastro-jejunostomy was illustrated by a paper from the pen of Mr. W. H. Brown, and by cases exhibited by Mr. Jessett, Dr. Ewart, and Mr. Bennett. Mr. Arbuthnot Lane described the results of two cases of resection of the intestine by Senn's method. Mr. Charters Symonds related instances in which sequestra were removed from the neck of the femur without injury to the joint. Dr. Maclagan narrated cases of peripheral neuritis in which the nerve lesion was followed by changes in the joints of the knuckles and fingers. Dr. Handford, using a case of gastrostomy, was able to make experimental investigation of the movements and contents of the stomach. Mr. A. Lane read the notes of eleven cases of laminectomy which he had performed for compression paraplegia resulting from spinal caries. Dr. Churton, in a case of hæmorrhagic pericarditis, had attained a successful result by repeated aspiration. Dr. Lee Dickinson and Dr. Fyffe drew attention to the subject of albumosuria. Dr. Pye-Smith gave the details of a case of mycosis fungoides in which there was a secondary visceral growth simulating sarcoma. The clinical significance of rapid heart was discussed, the subject being introduced by Dr. Buckland, with an illustrative case.

Among other communications of interest to various Societies were the following:—Dr. Playfair, in a paper on the removal of the uterine appendages in cases of functional neurosis, held that the procedure was not justifiable in cases of pure neurosis, was not to be recommended in hystero-epilepsy or hystero-mania, and that, if structural disease of the appendages co-existed, the neurosis should be treated first in the hope that operation may be avoided. Dr. Herbert Spencer gave a valuable contribution to the study of the causation of still-birth, relating the results of 130 necropsies and pointing out the frequency of visceral hæmorrhage. Dr. F. J. McCann described six cases of chorea gravidarum, and gave an account of

Digitized by Google

the modifications of that disease during pregnancy. Dr. Herman discussed the relation between backward displacement of the uterus and sterility and abortion. Mr. W. A. Brailey read a paper on some points of the development of cataract, giving the results of analysis of a large number of cases. Miners' nystagmus among the South Wales colliers was discussed by Mr. Tatham Thompson, who considered that visual strain with insufficient illumination was as great a causative factor as strain of the ocular muscles, and that errors of refraction were predisposing causes. Mr. Treacher Collins made some very valuable observations on the glands of the ciliary body in the human eye. He had prepared his sections by bleaching them with chlorine. Mr. Richard Williams read a description of an interesting case of arterio-venous aneurysm of the orbit. Dr. Mules described the formation and pathology of pyramidal and central anterior capsular cataracts. Dr. Bronner gave notes of fifty cases of strabismus trea ed by advancement of a rectus muscle according to the method advocated by Schweigger. Mr. Kenneth Scott found that perchloride of mercury was of value in the curative treatment of trachoma and other conjunctival diseases. Dr. Beevor and Mr. Horsley related a case of traumatic abscess of the left angular gyrus, with right hemianopsia and word blindness, which was treated by operation. Dr. Edward F. Willoughby compiled a retrospect of the successive epidemics of cholera in Europe and America from 1830 to 1890. Dr. Dreschfeld described a case of acute lympho-sarcomatosis in which the course of the disease was very rapid and the blood appeared to be flooded with cells like those seen in lympho-sarcoma. Dr. Buxall emphasised, by means of an illustrative case, the fact that sepsis could occur after childbirth without fetor. Dr. Bewley read a statistical paper on the diagnostic significance of venous hum in the neck, in which he confirmed the conclusions previously arrived at by Apetz. Dr. Woodhead dealt with the question of the relation of modification of function of micro-organisms to the virulence and spread of specific infective diseases. Dr. Campbell Munro produced an epidemiological study of measles. Dr. M. A. Boyd, discussing the etiology of Cheyne Stokes respiration, reviewed all the physiological explanations of this phenomenon offered by writers on the subject since Stokes' time to the present day. Sir William Stokes gave his valuable experience of operations on the thyroid gland. Dr. Hingston Fox introduced for discussion the subject of albuminuria in relation to life assurance. The President of the Royal Academy of Medicine of Ireland introduced a valuable discussion before that body on the operative treatment of uterine cancer. Dr. Leith Napier, discussing the subject of the treatment of habitual abortion, urged the value of local measures, together with the prolonged exhibition of mercury. Mr. Bryant, in his capacity of outgoing President of the Harveian Society, delivered an able address on the treatment of internal intestinal strangulation and obstruction. The subject of the present position of disinfection was ably discussed by Mr. Wynter Blyth. Sir Charles Cameron drew attention to cases of illness caused apparently by eating aniline-coloured sweetmeats. Fuchsine was the dye used, and the author thought that it might be toxic even when free from arsenic. Dr. Louis Parkes read a very suggestive paper on the relations of saprophytic to parasitic micro-organisms. Dr. E. S. Reynolds related an instance of so-called spontaneous combustion, and classified all the reported cases. Dr. Hellier advocated abdominal section for pelvic abscess, where there was no pointing obvious in rectum, vagina, or groin.

Many discussions on the value of the "Koch" treatment for tuberculosis took place both in London and in the provinces, and a large number of cases that had been under treatment were shown. The "clinical evenings," as heretofore, have been an unqualified success, and the meetings devoted especially to discussions have been very fully attended.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 3794 births and 4106 deaths were registered during the week ending Dec. 26th. The annual rate of mortality in these towns, which had declined in the preceding three weeks from 22·6 to 19·1 per 1000, rose again to 22·8 last week. The rate was 21·9 in London and 23·5 in the twenty-seven provincial towns. During the first twelve weeks of the current quarter the death-rate in the twenty-eight towns averaged 19·9 per 1000, and was 1·5 below the mean rate in the corresponding periods of the ten years 1881–90. The lowest rates in these towns last week were 13·2 in Leicester, 16·4 in Huddersfield, 16·5 in Birmingham, and 16·9 in Hull; the highest rates were 27·0 in Sunderland, 27·1 in Manchester, 28·1 in Liverpool, and 45·1 in Newcastle upon-Tyne. The deaths referred to the principal zymotic diseases, which had declined in the preceding three weeks from 477 to 395, rose again last week to 461; they included 170 from measles, 167 from whooping-cough, 39 from scarlet fever, 34 from diphtheria, 26 from "fever" (principally enteric), 25 from diarrhœa, and not one from small-pox. No fatal case of any of these diseases was registered in Brighton or in Halifax; in the other towns the lowest zymotic death-rates were recorded in Portsmouth, Bristol, and Hull; and the highest rates in Bolton, Manchester, Liverpool, Wolverhampton, and Newcastle-upon-Tyne. The greatest mortality from measles occurred in Derby, Manchester, Sunderland, Wolverhampton, Newcastle-upon-Tyne, and Cardiff; from scarlet fever in Huddersfield; from whooping-cough in London, Manchester, Wolverhampton, Blackburn, Bolton, and Newcastle-upon-Tyne; and from diarrhœa in Preston. The mortality from "fever" showed no marked excess in any of the twenty-eight towns. The 34 deaths from diphtheria included 20 in London, 4 in Liverpool, 2 in Manchester, and 2 in Newcastle-upon-Tyne. No fatal case of small-pox was registered in any of the twenty-eight large towns; one small-pox patient was under treatment on Saturday last in the Metropolitan Asylum Hospital at Dartford, but not one in the Highgate Small-pox Hospital. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1465, against numbers declining from 1554 to 1489 at the end of the preceding three weeks; 90 new cases were admitted during the week, against 137 and 109 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding three weeks from 449 to 337, rose again last week to 553, and exceeded by 51 the corrected average. The causes of 92, or 2·2 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Newcastle-upon-Tyne, Cardiff, and in four other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Halifax, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the preceding three weeks from 32·2 to 26·0 per 1000, rose again to 27·1 during the week ending Dec. 26th, and exceeded by 4·3 the mean rate that prevailed during the same period in the twenty-eight large English towns. The rates in the eight Scotch towns ranged from 22·0 in Perth and 23·0 in Leith to 29·6 in Paisley and 30·6 in Aberdeen. The 698 deaths in these towns showed an increase of 29 upon the number in the preceding week, and included 16 which were referred to whooping-cough, 11 to diarrhœa, 5 to measles, 4 to scarlet fever, 4 to diphtheria, 1 to "fever," and not one to small-pox. In all, 41 deaths resulted from these principal zymotic diseases, against 59 and 50 in the preceding two weeks. These 41 deaths were equal to an annual rate of 1·6 per 1000, which was 1·0 below the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 18 and 12 in the preceding two weeks, rose again last week to 16, of which 5 occurred in Glasgow and 4 in Aberdeen. The 11 deaths from diarrhœa corresponded with the number in the previous week, and included 4 in Dundee, 3 in Glasgow, and 3 in Edinburgh. The 5 fatal cases of measles were all recorded in Glasgow. The deaths from scarlet fever, which had steadily increased in the preceding four weeks from 4 to 11, declined again to 4 last week, of which 2 occurred in Edinburgh. The 4 fatal cases of diphtheria corresponded with the number in the previous week, and included 3 in Glasgow. The deaths referred to diseases of the respiratory

Digitized by Google

organs in these towns, which had declined from 331 to 246 in the preceding three weeks, rose again last week to 254, and exceeded by 72 the number in the corresponding week of last year. The causes of 64, or more than 9 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·2 and 33·9 per 1000 in the preceding two weeks, declined again to 29·1 during the week ending Dec. 26th. During the past twelve weeks of the current quarter the death-rate in the city averaged 28·5 per 1000, against 18·7 in London and 25·8 in Edinburgh. The 194 deaths in Dublin during the week under notice showed a decline of 32 from the number in the previous week, and included 9 which were referred to different forms of "fever," 5 to whooping-cough, 2 to diarrhœa, and not one either to small-pox, measles, scarlet fever, or diphtheria. In all, 16 deaths resulted from these principal zymotic diseases, equal to an annual rate of 2·4 per 1000, the rate during the same period being 2·9 in London and 1·4 in Edinburgh. The fatal cases of "fever," which had been 11 and 7 in the preceding two weeks, rose again to 9 last week. The deaths referred to whooping-cough, which had increased from 2 to 4 in the previous three weeks, further rose to 5 last week. The 2 fatal cases of diarrhœa were below those recorded in any recent week. The 194 deaths registered in Dublin included 31 of infants under one year of age, and 57 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from the numbers in the preceding week. Three inquest cases and 2 deaths from violence were registered; and 62, or nearly a third, of the deaths occurred in public institutions. The causes of 18, or more than 9 per cent., of the deaths in the city were not certified.

"Audi alteram partem."

SHAKESPEARE'S DEATH.

To the Editors of THE LANCET.

SIRS,—Although a little belated, I would fain make, with your permission, some remarks on the recently revived speculations as to the mode of death of one of the world's greatest men. For every intelligent lover of English literature, or even for every admirer simply of Shakespeare himself, the question of the dramatist's early death must ever have a keen though regretful interest. And it is little wonder that the modern spirit of scientific medicine should specially seek to utilise the results of accumulated research and observation in trying to explain the hitherto death-mystery of Shakespeare. But here we are face to face with a deplorable illustration of the saying that "the world knows little of its greatest men"; and as to the cause of Shakespeare's death we do not know, and are not likely ever to know, anything at all. For absolutely the only thread of information as yet known to exist, from which to weave any reasonable hypothesis, is unfortunately so slender and trashy as to be utterly worthless. The Rev. John Ward, Vicar of Stratford, as was not uncommon in those days, seems to have acquired a smattering of medical knowledge sufficient to induce the bishop of his diocese to grant him also a licence to practise medicine; and this clerical dabbler in physic and gossip, this "chronicler of small beer," close on half a century after the poet's death, resolved to immortalise himself by associating his name with Shakespeare's and giving to posterity some "facts" about the great Stratford man's history. These statements are embodied in his "Diary" under date 1662—a chronicle, no doubt, composed of a "halfpennyworth" of truth to an "intolerable deal" of gossip. The "facts" which he gravely records concerning Shakespeare's life are known to be very wide of the truth, and mere popular garbage; and the account of his death has on it the stamp of the same base coinage. He evidently knew nothing definite about the poet, his life, his works, his real nature and character, or his death. Indeed, the discerning student of Shakespeare has to-day a much better knowledge of the man Shakespeare, from his works and some authentic records, than Ward could have had. And, in my opinion, it is unquestionable that, after an appreciative and careful study of Shakespeare's whole works, no one can willingly entertain the suggestion that this man of noble mind and well-balanced character, of whom it might be said in his own words—

> "His life was gentle; and the elements
> So mix'd in him, that Nature might stand up
> And say to all the world, 'This was a man'";

who to the sanest sense and practical knowledge of the world and of the human heart united the first intuitions of the imaginative faculty and a profound respect for moral dignity; who, after twenty years of most copious literary production of such high quality, which scarcely can be reconciled with much dissipation, had retired to his own property in his native town to enjoy a life of refined leisure and some social dignity, and where, it is certainly ascertained, he was greatly respected and honoured: that this man, on the occasion of entertaining two of his oldest and most cherished friends, should give himself over to a drinking bout and guzzle himself into a "fever." The Rev. John Ward could not have held Shakespeare's memory in very high respect to accept and record for truth the vulgar slander of prejudiced ignorance and popular chatter; and it is highly probable that he did not, for the stage had little mercy shown it in those days, especially by the Church, and he would know little and care less about the playwright, his reputation, or his writings. From the tenor of the testimonies, on the other hand, paid to Shakespeare by some of his contemporaries, it may reasonably be inferred that among a set of convivial actors and dramatic authors he himself was at least comparatively temperate. And, moreover, at the time of his death he was surrounded domestically by a religious and even puritanic atmosphere, which would hardly be compatible with indecent conviviality in his own house. With your own remark that he himself in his writings lends some plausibility to the story I can scarcely agree; for it is one thing to be a creator of characters and a close observer of men, using material as an artist for true and realistic human effects, and quite another to be the character delineated. And it must be remembered that he has a Cassio as well as a Falstaff, a Prospero as well as a Caliban. The visit of Ben Jonson and Michael Drayton may be accepted as very probable, and by no means the first or only one, if unfortunately the last; and it is quite possible they may have had a "merry meeting" and taken too much. But they did not take "fever," which was "there contracted" by Shakespeare. On the whole, this debauch incident must be entirely abandoned as totally improbable, untrustworthy, and unsupported. And yet your smart American writer—for smart he certainly is—largely founds his theory on the "deep intoxication" of Shakespeare as exposing him to a chill which leads on to pneumo-paresis. This "fundamental fact" must be regarded as having no foundation in fact. Your judicial Daniel has even improved upon Ward, who says nothing of "deep intoxication," and he has also taken for granted what is not stated, that the illness was a very short and rapid one. It must, however, be admitted that three months before his death the poet commenced his will with the words: "I, William Shackspear, of Stratford-upon-Avon, in the county of Warwick, gent., in perfect health and memory (God be praysed!)"; but two months later, that is in March, he attested the will with his signatures, and these certainly show much shakiness, as if some illness were already telling on his strength. And although a large proportion of deaths in the end of April of people of fifty years of age may be caused by respiratory mischief, there were many other things a man of fifty might have died of in a low-lying midland county in the early years of the seventeenth century, and just on the eve of May-day. Drayton was a year older than Shakespeare, and Jonson but ten years younger; and yet these good fellows both lived on for many years afterwards free from pneumo-paresis. It was not rare in a low-lying, sheltered place like Stratford, on the lush, level banks of a river, to have a course of warm, moist weather in late spring; and there appears to have occurred early in that spring, what was not unusual after the winter, an inundation of the river Avon. To the dwellers in Stratford, therefore, with its imperfect drainage, impure water-supply, and defective

Digitized by Google

sanitation generally, such a condition of things and combination of evil influences were surely not much less perilous than a sudden change of temperature or an east wind. And there is no certainty that Warwickshire was specially exposed to east winds in the end of April. Chaucer writes:—

"When that Aprile with his showres sote
The droughts of March hath perced to the rote,

When Zephyrus eek with his swete breth."

Besides, Dr. Hall mentions in his "Select Observations," published by Cooke, that the very year after his illustrious father-in-law died a "new fever" was raging in the town, and might possibly have begun in the place the year before; for it is matter of unspeakable regret that the notes of this physician begin most tantalisingly in the year after Shakespeare's death. What this "new fever" was—whether typhoid, epidemic pneumonia, influenza, or some modified phase of malarial or rheumatic fever—it is impossible to say from the evidence at command.

The only other link in the chain of this "drunk and dying" theory is that of the look of "ineffable sadness" which has been detected in the bust of the poet. Whoever discovered this melancholic aspect of the Stratford bust before? And even if it were found to exist, would it be exceptionally wonderful, rare, or strange, or necessarily suggestive of death from pneumonia? There is no doubt whatever that the author of "Hamlet" during his lifetime bore many a time and oft a look of "ineffable sadness" in his noble face without suffering from pneumonia. And I have certainly never known a physician who could diagnose death from pneumo-paresis by looking at the expression on the face of a cadaver; such quick-sighted divination has but rarely reached the schools as yet, and must be limited to a very few specially gifted medical seers. And surely pneumonia is not the only cause of a look of sadness in dead faces. The eyes have a trick of seeing what the mind is wishful to see; and the primitive makers of the original cast and the humble sculptor of the Stratford bust copied from it, could not have dared to hope that the double operation would result in such perfect and minutely accurate work as your American writer supposes he has found it to be. Altogether, this point of the pneumonic physiognomy, true to a certain extent as it may be, which has been gathered from a probably imperfect, though generally reliable, bit of sculpture, is much too refined, artificial, and forced for ordinary mortals. I am pretty sure that, like the "deep intoxication," it has no real existence.

I cannot see, therefore, that the writer in the New York *Medical Record* has at all made out his case, however ingenious his hypothesis may be. It is quite possible that Shakespeare died of pneumonia, just as it is equally possible that he may have died of typhoid fever, rheumatic fever, bronchitis, influenza, or malarial poisoning of some kind, for we have no idea whatever as to the length of his illness. Instead of a "jury of the present day," provided they had an intelligent acquaintance with the poet's character and works, reasonably finding a verdict of "Death from pneumonia," I have no doubt whatever, if the evidence were fully given and severely examined, that their verdict would still be "Cause of death unknown." I have merely to add that your correspondent Mr. Foy, who, like myself, disagrees with the new suggestion, though for a somewhat different and, in my opinion, erroneous reason, has not been altogether accurate in his statements. He mentions that the period covered by Ward's diary, 1648 to 1679, was that "in which Shakespeare enjoyed his leisure and died;" while of course the fact is that that period was from 1613 to 1616. And again, instead of Dr. Hall being an "important witness," as he might well have been, it is a pre-eminently lamentable fact that he is silent about the illness and death of his now world-renowned friend and patient. For it cannot be doubted that he was the medical attendant in Shakespeare's last illness. But no hint is to be found in his "Select Observations" bearing on the case of his father-in-law; possibly his notes previous to 1617 have been lost. So that any diagnosis drawn from his notes must be entirely imaginary or a hypothetical inference from some vague facts of the family history. It is true that among the rank-and-file of the profession in those days the term "pleurisy" was employed to designate most forms of inflammatory chest disease; but among the better educated and cultured of the physicians, among whom Dr. Hall has claims to be reckoned, the affection known as "peri-pneumonia" must have been familiar, as it is distinctly recognised, described, and named by the old medical writers who were their authorities. The word "fever" also covered many undiagnosed inflammatory diseases as well as the specific and zymotic ones.

I am, Sirs, yours truly,

D. BEATTIE BAIN, M.D.

Airlie-place, Dundee, Dec. 21st, 1891.

ANTISEPTICS IN OPHTHALMIC SURGERY.

To the Editors of THE LANCET.

SIRS,—In to-day's issue of THE LANCET there appears a letter from Mr. Bullar in which he throws considerable doubt upon the benefits resulting from the use of antiseptics in ophthalmic surgery, and in support of his opinion he refers to an experiment in which, in spite of the use of antiseptics and every care, the rabbit's eye—the subject of his researches—very soon decomposed. But, Sirs, this experiment, to my mind, proves nothing at all; he is dealing with dead matter, tissue absolutely devoid of resisting power through any vitality of its own; and, curiously, he describes this experiment immediately after having mentioned Dubief's interesting paper, in which is demonstrated the practical impossibility of rendering an eye operation aseptic—i.e., that, after repeated washings and treatment with antiseptics, germs capable of multiplying and setting up mischief could still be discovered in the tissues by the microscope. Then what, under such conditions, is it that allows of a successful result in any case? Should they not all fail? Is it not the inherent vitality of the tissues, the superior fighting power of the leucocytes, or other resisting forces, which prevent such a disastrous termination to every operation? But may not antiseptics have something to do with the successful result; may they not act as the skirmishers and sharpshooters in less mimic warfare, crippling the germs and making them very sick, so that they may more readily receive the *coup de grâce* at the hands of the leucocytes &c., or, at any rate, be rendered powerless to make a breech in their opponents' bulwarks? Is it not a fact that both pan-ophthalmitis and plastic iritis—those two bugbears after extraction of cataract, and both, in all probability, septic in origin—are decidedly less frequent than before the use of antiseptics? Do not the records and experience of our metropolitan ophthalmic hospitals, situated as they are in places where germs most do congregate, bear out this statement? I think so. Because many operations are successful, though carried out under other than antiseptic principles, it does not follow that antiseptics are of no use; they may, perhaps, be only really necessary in an odd case or two in which the inherent resisting power of the tissues is not great enough unaided to wage a successful war with their microscopic foes; but as it is impossible to know such cases from others, it behoves us to treat all with equal care, then we can have nothing to reproach ourselves with. Even a good swimmer would not feel any the less secure in either smooth or rough water with a reliable swimming belt round his chest.

I am, Sirs, yours faithfully,

S. JOHNSON TAYLOR, M.B., M.R.C.S.

Prince of Wales-road, Norwich, Dec. 19th, 1891.

"ACUTE RHEUMATISM AND THE TEMPORO-MAXILLARY JOINT."

To the Editors of THE LANCET.

SIRS,—In reply to Mr. Lane's letter in your issue of to-day, I would say that when I exposed (what I represented to be) his premisses and upset his conclusions, I did not, as he suggests, do it unintentionally. To misstate an opponent's argument is bad, but to misquote his statements is worse, and Mr. Lane has twice been guilty of this offence; in his first extract from my letter he writes "and *even* with rheumatic arthritis" instead of "and *never* &c." This, though, may be a clerical error, and as such I leave it; but when in his next quotation he writes, "why should that joint be affected alone" instead of "why should that joint *never* be affected alone" there can, it is plain from the context, be no such error as I have supposed above. I feel too that he

Digitized by Google

must have read my letter so carelessly as almost to justify me in not replying, for not only does he quote the sentence wrong, but he makes it refer to rheumatoid arthritis instead of acute rheumatism, as in the original it most clearly does. This correction is sufficient answer to that part of the letter following and founded on the above misstatement. I fear I am intensely dull, but I cannot grasp the line of reasoning as to comparative and complete degrees of tendency to affection of certain joints. If my logic was "pre-Baconian," Mr. Lane's may be termed ultra-Baconian. That I have misstated Mr. Lane's argument I quite deny. I repeat that in his first letter he practically said "that because the temporo-maxillary joint is often affected with rheumatoid arthritis, and never with rheumatic arthritis, therefore it alone can never be affected with acute rheumatism." For he wrote: "The *only* [the italics are mine] connexion which is in my mind allowable is between affection of this joint and rheumatic arthritis." The only proof he adduces in support is the subsequent part of his letter, where he states that according to his observation the temporo-maxillary joint never is affected with rheumatic arthritis, and that it is very frequently the seat of rheumatoid arthritis—so often, in fact, that "the disease may be diagnosed with comparative safety by terming it rheumatoid arthritis should the temporo-maxillary joint be at all affected." I first wrote pointing out that I thought your correspondent had not sufficient grounds to upset Dr. Gallipe's diagnosis, as the statements in his first letter were all he brought forward to support his contention, and as there was evidence in Dr. Gallipe's report against rheumatoid arthritis and in favour of acute rheumatism, I can only repeat what I first said. In answer to Mr. Lane's last paragraph, his letter is certainly quite "enough," though not right enough, to show me any chimera of my own creation.—I am, Sirs, your obedient servant,

Freshford, Dec. 26th, 1891. CHARLES E. S. FLEMMING.

To the Editors of THE LANCET.

SIRS,—Apropos of some recent communications in your widely read journal on the above subject—Oct. 24th and Nov. 14th, 1891,—I would like to add the following peculiar case, also some few remarks and deductions from some recent experience, to me appearing to add weight to the microbic theory of the origin of the disease. A sailor, aged twenty-seven, employed as a guard over unruly and incorrigible apprentices, was suddenly taken ill in the night with shiverings and general pains. He presented himself for treatment on the following morning. He had only a moderately high temperature (101·5°), complained of pains in his back, neck, and principally in his jaws. Upon examination the temporo-maxillary joint was very tender, swollen, and mastication or movement of the jaws was impossible. He was known to be living under insanitary conditions most of the time, and there was suspected serious disease, possibly tetanus. He was isolated and placed under conditions of extreme quiet and careful management. On the third day the joints of the lower extremities manifestly became involved, the jaws could be opened slightly, and as no spasm of muscle or nervous phenomena occurred, the case was recorded as one of ordinary acute rheumatism and treated accordingly. It was next discovered that the patient had gonorrhœa, and the affection was thus finally placed in its proper category. It went on for a month, as a more or less painful inflammatory and septic affection of the ligamentous tissues of the body. The temporo-maxillary joint and contiguous structures, the hip and knee-joints, caused most anxiety and pain, and in the order named. The temperature averaged 102°, with a daily evening rise; the perspirations were constant; the urine not changed beyond being concentrated; and the pains exquisite, and requiring large amounts of narcotics and anodynes to keep him from crying out constantly. He was treated with alkalies, salicylates, quinine, and hot baths, the urethritis receiving proper attention. After using large doses of morphia, bromides, chloral, &c., with only partial success, to relieve his acute sufferings, we found that by using the ext. cannabis indica, in half-grain doses, for several hours, and at sundown a full dose of sulphonal in a large draught of hot water, painless sleep was procured. Now this was a case produced by an antecedent specific urethritis without a doubt. I have seen many cases of what we call "gonorrhœal rheumatism," but not one with such peculiar temporo-maxillary initiatory pronounced symptoms simulating a tetanoid condition of the neck and jaws. From some acute rheumatisms in my experience, not connected with gonorrhœa, but following an ulcerated tonsillar condition, I am inclined to believe that this disease is a septic or toxic infection pure and simple, and may be in the great majority of instances so demonstrated satisfactorily. When once these structures and tissues become disordered—the fibrous tissue—the liability to future exacerbations remains. This liability is most pronounced when the disease follows a specific urethritis. The cases following ulcerated tonsils showed not much fever or general articular lesion beyond moderate swelling, pain, and for short periods of time; and the symptoms were promptly controlled. The striking point, and a most serious element in the prognosis in these cases, is the strong tendency to lesion of the cardiac valves, notwithstanding every precaution employed. Whether a patient with vulnerable tonsils is also vulnerable at the cardiac valves is of importance, but I have been struck with these cases of moderately severe acute rheumatism following ulceration of these glands in the throat, and the sequence of disease of the heart valves.

In the contention whether acute rheumatism is or is not a germ disease, or, in other words, of microbic origin, the study of such variations in the course of the disease, when apparently following, and a sequence of, purulent inflammation of a mucous membrane, is of valuable interest and importance. It is not probable, if I may hazard the thought, that a single species of bacterium is the sole cause; or that all subjects are equally susceptible to the pathogenetic influence or toxicity of the pus organisms, or of an as yet unknown micro-organism, acting singly or in association; yet that the toxic influence is evolved during such suppurative inflammation of mucous membrane and glandular tissue, in which the well-known pus organisms chiefly figure, is in my observation a strong probability.

I am, Sirs, yours truly,

C. A. SIEGFRIED,

Newport R.I., U.S. America, Dec., 1891. Surgeon U.S. Navy.

CURIOUS ACCIDENT: A WARNING TO PRACTITIONERS

To the Editors of THE LANCET.

SIRS,—On the evening of the 27th ult., when about to examine an infant's chest with my binaural stethoscope, unobserved by me the left ivory ear-piece dropped off. I let the instrument go into the ear in the usual way, and the spring being somewhat strong, the uncovered end pierced my membrana tympani with a fearful crash. I shall never forget the sensation! For a moment I thought an explosion had taken place, shattering the wall on the left side of me, and for an instant felt stunned. This was followed by nausea. About a teaspoonful of blood flowed from the ear. The next morning Sir W. Dalby did me the kindness of inspecting the damaged membrane, endorsing the diagnosis expressed above, and put me on a line of treatment for the injury. Curiously enough, to-day (Dec. 29th) I described the case to a medical friend who had precisely the same accident occur to him, but without such a serious result, and, strange to say, both our stethoscopes were made by the same firm of instrument makers, and the cause of the accident was the same in each—viz., too short a screw fixing the ivory ear-piece on to the metal work. In my instrument there was only one turn and a half of "thread" to the screw, which had served well for a time, but in opening the instrument the slight hitch had apparently jerked the ear-piece off, and this falling just as I was about to insert the tube into the ear escaped my notice to my cost. My object in writing this will be obvious to both practitioners and instrument makers, cautioning the one class to look to their fittings and the other to see that their workmen really do their work well. Of your usual kindness in promoting the welfare of the medical profession, both individually and collectively, I am well aware, and on this point of knowledge I beg to trespass on your valuable space in bringing this accident before my medical brethren.

I am, Sirs, yours truly,

London, Dec. 29th, 1891. A GENERAL PRACTITIONER.

THE CORPUS LUTEUM.

To the Editors of THE LANCET.

SIRS,—I do not know whether my friend Dr. Robert Lee will be inclined to place me in the rank as one who has had

Digitized by Google

experience of the kind required to justify an expression of opinion upon the much-vexed question of the corpus luteum or not, but I am perfectly confident that I have made sections of more ovaries concerning the actual history of which the facts were known than any man alive. I have only to say that my conclusion long ago made, and confirmed by every investigation which I have made, is that the belief that the corpus luteum is altered in any way by pregnancy, or that there is such a thing as a true corpus luteum or a false corpus luteum in relation to the fact of pregnancy, is one of the most extraordinary crazes which has crept into medical belief, and it has been productive of a very large amount of mischief. It is one of those assertions which has been made in the early investigation of ovular physiology and pathology, based on the assumption that ovulation is a monthly occurrence, and it has been handed down from writer to writer without any kind of substantiating proof, whilst the negative evidence against it is perfectly overwhelming.

I am, Sirs, yours truly,

Birmingham, Dec. 30th, 1891. LAWSON TAIT.

TRAUMATIC HYDRONEPHROSIS.

To the Editors of THE LANCET.

SIRS,—Under the above heading in your issue of Dec. 19th Dr. J. J. Knox describes a very interesting case, and refers to three descriptions of such cases in THE LANCET during the last ten years. If he will refer to the "Mirror" columns of THE LANCET for Sept. 12th, 1891, p. 612, he will find a very similar case recorded by me under the title of "Traumatic Renal Cyst." In that case a boy aged six was struck on the front of the abdomen, and five months later a large swelling was found in the right loin. This remained unaltered for six months, and was then aspirated by Mr. Paul Swain at the South Devon Hospital, Plymouth, an absolute cure resulting from this single tapping. There are two points to which I wish to draw attention—1. The operation performed by Dr. J. J. Knox. In a case where the history and symptoms so clearly pointed to the tumour being a fluid cyst due to contusion of the kidney, would it not have been safer first to have attempted to cure the urinary effusion by aspiration, and that failing, by lumbar incision, by which means the cavity is much better drained and the peritoneum not opened? The fact of a single aspiration being sufficient in our case I think proves that this measure in all similar cases should be first resorted to. 2. As to the name of the condition. Nearly if not all these cases of so-called traumatic hydronephrosis are really extravasations of urine around the kidney from a rupture of the kidney involving its pelvis. The urine is therefore behind the peritoneum. The term hydronephrosis ought to be restricted to cases of dilatation of the pelvis and calyces of the kidney due to obstruction to the outflow of the urine. Would it not be better, therefore, to call these traumatic cases by the name "retro-peritoneal extravasation of urine?"

I am, Sirs, yours faithfully,

Dec. 24th, 1891. W. GIFFORD NASH.

THE AFTER-TREATMENT OF PLASTIC OPERATIONS ON THE PERINEUM.

To the Editors of THE LANCET.

SIRS,—Dr. Griffith is undoubtedly right in laying stress on the importance of accurate apposition of the wound surfaces and edges in these operations; but however complete the success of this stage of the operation may be, it cannot protect the wound from the entrance of septic infection if the edges of the wound and the surrounding parts are soiled with decomposing organic matter. Bathing the parts externally cannot protect the wound from the influence of urine within the vagina if it is allowed to get, and to remain, there. It is an almost universal practice to prevent separation of the patient's thighs, while the wound is healing, by passing a binder round the knees. When micturition is performed under these conditions the stream of urine cannot pass away clear of the vulva as it should do, and the vulva and perineum are almost always wet in the act. Placing the patient in the prone position would not cause the urine to pass away clear of the vulva, and would have the disadvantage of risking an undue strain being put upon the wound in turning the patient over and back again. On the other hand, the douche can be administered with no greater disturbance of the patient than is involved in raising the pelvis two or three inches for a moment. The douche has this further advantage in cases of retention, that, acting as a hot antiseptic fomentation to the wound, it at once allays the irritation which, in most cases, is reflexly causing temporary difficulty in relaxing the sphincter of the bladder, and so obviates the necessity for passing a catheter.

I am, Sirs, faithfully yours,

Hanley, Dec. 21st, 1891. ARTHUR E. NEVINS.

INCREASED DIRECT REPRESENTATION.

To the Editors of THE LANCET.

SIRS,—I have just read Dr. Wilks' letter in this week's issue of THE LANCET with much interest. He lays down the fact that the General Medical Council was appointed to supervise medical education and registration, in order that the public might be supplied with "fully educated medical men." This is an undisputed fact. There was another purpose, however, for which the Council was appointed—viz., to watch over the moral character of the registered practitioner, and, if he acted wrongly, to expunge his name from the Register—i.e., they were appointed to maintain a moral as well as an intellectual standard *for the welfare of the public*. How has this work been done? Let us glance for one moment at the present state of the profession. Let us look at the consequences of the small fee system. 1. So many patients have to be seen in order to make a livelihood (self-preservation being the first law of nature) that sufficient time cannot be given to the diagnosis of each individual case. This leads to unsound treatment, or in many cases pure quackery, and the public suffer. 2. Many scientific, highly qualified, and high principled men have been driven out of the profession, in which they found themselves handicapped by their conscience, into some other pursuit, where, in the words of the labour orator, "a fair day's wage is given for a fair day's work." Those who can go, and those who cannot remain, and often are driven by dire necessity to improper conduct. 3. Poorly qualified, or in many cases absolutely unqualified, assistants are doing the work which the authorities and the public fancy is being done by properly trained men. Again the public suffer. These facts are known to every general practitioner in the land.

What is the attitude of the Council? Sir William Turner is reported to have said that "he hoped he should always sympathise with the struggles of those who were beginning professional life; but he entirely failed to see what the hardships and struggles of the poorer members of the profession had to do with this question."[1] Sir Dyce Duckworth is reported thus: "In what direction had the best interest of all parts of the profession been neglected at the Council?"[2] Sir John Simon as follows: "The Council was not called upon in any vague sense to promote the welfare of the profession."[3] Dr. Wilks says in his letter: "Finally, I have not heard one good reason why more general practitioners are required on the Council."

I can only say that the report on the debate in Council of Nov. 26th, 1891, gives one excellent reason—viz., that the representatives of the examining bodies are out of touch not only with the profession, but also with the public, whose interests they were appointed to watch over. The members of Council who spoke referred the direct representatives to Parliament, but there still remains the right of appeal by the practitioners of England to the Privy Council. If either of these courses is forced upon the practitioner, then reform (i.e., restoration of the profession to a state of purity and usefulness) is taken out of the hands of the profession and placed in those of the laity. Surely, this is not a question of slight moment, but is of vital importance to the public weal.

I am, Sirs, yours faithfully,

CHARLES PATTERSON, M.B., M.R.C.S.

City-road, E.C., Dec. 16th, 1891.

THE MEDICAL DEFENCE UNION.

To the Editors of THE LANCET.

SIRS,—The proposed alterations in the articles of the Medical Defence Union are retrograde and revolutionary in character. Although the report of the committee, which prepared the new articles, was on the agenda of the last Council meeting in London, it was withheld at the last moment for some ostensible reason. Hence it becomes necessary for me to appeal to the whole body of members. I shall merely allude to the introduction of a section into the new articles to prevent the annual meeting from petitioning against legislation injurious to the profession, as it did last time, contrary to the wishes of our valued, though somewhat self-opinionated, president. I believe this attempt to restrict the Memorandum of Association to be futile and illegal. The really serious matter, however, is the proposed change in the management of the Union. Hitherto all the officials and the Council have been directly responsible to the Union itself, each individual requiring annual re-election. This self-governing system has worked well and the Union has flourished. Now all this is to be changed. At the next annual meeting twelve members of Council are to be elected, and to them will belong the power of electing all the officials, the president of the Union, and as many vice-presidents as they choose. Nor are the twelve to be responsible to the Union by requiring annual re-election. They are merely to select from their number any three they choose to retire, or stand their chance of re-election. Now, suppose that the Council adopted a policy contrary to the wishes of the Union: an annual meeting could elect three members of Council opposed to such policy; but the Council can neutralise their influence by its election of vice-presidents &c. Briefly, the twelve members of Council elected at the next annual meeting under the new articles will have absolute and practically irresponsible control of the Union. The Council has power to act for the Union, and the acts of the Council are as the acts of the Union. This is a plain statement of facts, and I appeal to the members of the Union to pause before they hand over their powers to any twelve of their number. I believe that such a step will prove disastrous to the Union.—I am, Sirs, yours faithfully,

HUGH WOODS, M.D.,
Vice-President of the Medical Defence Union.

Highgate, Dec. 22nd, 1891.

INFLUENZA.

To the Editors of THE LANCET.

SIRS,—After reading the paper by Dr. Althaus on Grip and the letters of some others on different aspects of the same affection, I am tempted to reiterate the one or two points I ventured to bring forward in my note to you three or four months ago, in which I suggested that for a nervous fever of which the characteristic and diagnostic symptoms are to be found in tracts supplied by the trigeminal nerve, trigeminal fever is a truer and more connotative name than either grip (which is by no means universally descriptive of this disease, and might indeed, with as much or more propriety, be applied to other affections) or influenza (which is confessedly confusing and usurpative). Again, if there be anything in theory of eye infection or in collyrium treatment, then still more fitting becomes this term, "trigeminal fever." The point upon which I desire evidence, with your kind assistance, is the following:—In the few hundred cases seen by me during this present year the one single diagnostic point has been in the upper gum and labial frænum; this, indeed, has seemed as typical and decisive as one symptom can be of one disease. Skeptomai means: "I look that I may see." Surely no man has the right to be sceptical in loose, conventional parlance, unless he be such in derivative sense. Perhaps Dr. Althaus would prefer the term "bulbar fever"; but this implies a theory which, however probable, is not quite proven.—I am, Sirs, yours faithfully,

Hastings, Dec. 14th, 1891. G. HASSALL HUNTLEY.

NEW COTTAGE HOSPITAL AT LEDBURY.—Mr. M. Biddulph, M.P., has presented to the town of Ledbury, in commemoration of the coming of age of his eldest son, Mr. John Biddulph, a cottage hospital, at a total cost of about £3000.

THE ORIGIN AND INSPIRATION OF "THE LANCET."

WE are indebted to an old and esteemed correspondent for the following article, which will, we are sure, be read with interest:—

The condition of the profession of medicine prior to and at the time of the founding of THE LANCET has been much traversed, and writers of the period have pointed out that in the hospitals as well as outside them there existed abuses such as would not be tolerated at the present day. Monopolies, cliques, time-servers, and place-hunters abounded, hindering most egregiously the progress of medicine as a science and the career of the medical student as an individual. Colleges and universities were not much in advance of the average state of matters, and, in some instances, it appeared that the unsatisfactory condition of the body medical was mainly attributable to their conduct. Metropolitan hospitals existed, as they do now, for the benefit of the poorer classes of the community, and collaterally to aid in the acquirement of a sound medical education. But they were practically closed to the medical profession. Men were appointed by influence to important positions in them who had "neither eyes to see, ears to hear, nor tongues to teach." That anyone should enter a hospital for the purpose of making notes of a lecture for publication was considered to be a species of poaching. The "game laws of physic" were as stringent as the laws relating to hunting in the time of William the Conqueror. The lecture was a secret—a mysterious thing of wonderful erudition—to the outside world, and even to many members of the profession. No one benefited from the opportunities of investigating disease clinically save those who were fortunate enough to have obtained one of the hospital appointments, oftentimes through the payment of vast fees to the leading members of the hospital staff. The public had no means of judging whether things were well managed or mismanaged within the walls of these medical sanctuaries. The medical profession was kept profoundly ignorant of what was in progress there. The student was neglected, any clinical instruction worthy of the name had not yet been called into existence, and the medical prescriptions were models of mystery.

This was the condition of matters in the metropolitan hospitals at the time when Napoleon the Great was on the island of St. Helena, a period renowned for the discussion of the question of the liberty of the Press, when Pitt the younger was Premier. It was a period of reformers, though many who began as such turned tail on discovering a policy which paid better. Men were replacing slaves in the colonies, and Cobbet was advocating political reforms at home. At this period a young student from the county of Devon enrolled his name in the archives of St. Thomas's Hospital. His robust appearance, athletic limbs, and general manly bearing, no doubt developed by two years' seafaring life in the Indian merchant service as a midshipman, attracted the attention of some of his teachers, and shortly afterwards became a favourite with the majority of his student colleagues. He was descended from the Celtic stock, the pure old British blood flowed in his veins, and he possessed all the essential qualities of the Celt — fire, impetuosity, strength, that courage which means manhood, the standing up for rights and doing battle in a noble cause. These were some of the qualities which young Wakley brought with him from the country hearth to the hospital on his entrance to the medical profession. His observation was keen, and he was soon speedily and painfully alive to facts of the kind which I have recorded above. He went through the dreary routine of the hospitals and the schools of that period and his spirit was stirred within him as he perceived in all quarters efforts to impart medical knowledge according to methods that a Highland schoolmaster of the last century would have been ashamed of. As

Digitized by Google

time went on the abuses to be rectified grew upon his mind with greater and greater intensity. He determined that the abuses so manifest should be rectified if possible. Things medical had come to a critical period. The tension between the various medical bodies was so strong that Mr. Wakley could not fail to observe it, the strong feelings which existed between the more thoughtful of the students and those responsible for the scant and often improper use which was made of the material at their disposal for their instruction, and, above all, the acute condition of matters between hospital teachers and the medical profession generally, started the train of thought which caused the name of this young student in after years to become synonymous with the champion of medical reform. The task he set himself was to remove, if possible, those conditions which had given rise to the high tension in the body medical. It required, he said, treatment similar to that upon which in our forefathers' time the physician relied for the disappearance of those morbid products, or "humours" as they were called, and which often led in the case of disease to complete recovery. Could the body medical be made subject to treatment of this kind. If so, it might be possible to bring about a profound change in the system of things as they then existed. Hence the origin of THE LANCET. This little instrument of steel, which, though now serving for the most part as a decoration for students' pocket-cases, must have afforded, according to high testimony, great relief to our forefathers, and, in many cases, must have prolonged life, notwithstanding the fact that Lord Byron has credited it with having slain more than the soldier's lance.

The action of the lancet was never punitive, but conservative of life and energy, and an agent used to purify the body from those deleterious products upon which its mortal ills depended. It occurred to Mr. Wakley that, by using the quill for purposes similar to those for which surgeons used the lancet, he might, in the body medical, get rid of much that was harmful; and, instead of its members tottering with premature decay, despised by all men, they might obtain a new lease of life and vigour, and be of greater service to the people in the country at large. Accordingly, in the year 1823, his energies were thrown with full power into a publication which was then indeed a "tiny instrument," and he issued, on the 5th of October of that year, the first number of THE LANCET. It extended only to thirty-six pages, but its effect was startling in the extreme; though tiny, yet so sharp and penetrating were the articles in this number, and withal so bold, that many were astonished at the apparent audacity of the little number. The comfortable hospital doctors beheld its appearance with trepidation. Quacks held their breath, malpractitioners were in alarm, and the medical public were quiet and expectant. Its statements and criticisms were courageous and full of manly vigour, and it sounded in medical literature a stirring note altogether different from the tone of its tame predecessors.

In illustration of the correctness of these statements a brief sketch of the contents of this first number of THE LANCET, published on Oct. 5th, 1823, at 6*d.*, by A. Mead, 201, Strand, will be sufficient. The preface expresses regret that no work existed which would convey to the public, to distant practitioners, and to students reports of the metropolitan hospital lectures. Then follows a surgical lecture, delivered on Wednesday, Oct. 1st, 1823, in the theatre of St. Thomas's Hospital, by Sir Astley Cooper, at which over 400 students were present, describing the duties of the profession, and advocating the practical aspect of medical education. General education was stated to be essential to the welfare of the profession. This lecture was reported specially for THE LANCET, and led to a prolonged struggle, which only terminated in the law courts. Then comes a section headed "Politics," with a sketch of Mr. Pitt the younger, who is described as "a character to whom England owes anything but gratitude. His admirers in rapture called him in his twenty-third year the boy statesman, and in his forty-seventh he was still the same, running after wild, impracticable schemes regardless of everything but the gratification of his own senseless and petty ambition." An intimation follows of the intention of THE LANCET to publish in the next number particulars of a case which excited much attention at the time—namely, that of Dr. Collyer. Interesting criticisms of the drama are next given from Drury Lane and from Covent Garden. In the medical and surgical intelligence, Henry Earle defends himself from Sir Astley Cooper's reply to his critical observations on fracture of the neck of the femur, of which Sir Astley, when he read them, was led to exclaim, "Good God! is this written by an English surgeon?" Next there is an account of a case of anasarca successfully treated by acupuncturation, in which "the arms and trunk were reduced in the course of a week to their natural size." A case of hydrocephalus chronicus in which pressure proved most beneficial is recorded by J. F. Barnard, Esq., of which the following gives the gist: "I had the head shaved perfectly clean. I then applied broad strips of adhesive plaster completely round the head from before backwards, and cross strips from the one side to the other, so as effectually to support the parietes of the cranium. Having decided on my practice, I waited patiently the result." The article ends: "It is now two months since the bandage was applied, and the child is in every respect healthy except that the head still contains water, and is larger than it ought to be. I shall recommend the bandage to be worn until the bones are fully united." What would be thought of such a procedure now? Mr. T. M. Greenhow, surgeon, records a case in which hydatids were discharged in considerable quantities from the intestines. They were of various sizes and of different colours, very nearly resembling boiled gooseberries and of about the same dimensions. An interesting ancient notion of the physiology of respiration is given in a paper on Obstruction of Blood in the Lungs, reprinted from the *Edinburgh Medical and Surgical Journal*, in which an attempt is made "to convince a person that the blood stagnates in his lungs every time he interrupts his respiration by uttering long sentences, and that that interruption endangers the rupture of a blood-vessel or engenders tubercular consumption." A remarkable illustration of the fatal effects of fear in the operation room, and a few medical extracts of an interesting character, are followed by an account of the composition of quack medicines, and three columns of table talk. The number concludes with a remarkable article on Southey, the Poet Laureate, in which he is set forth as a "Sack-hunting, hypocritical rhymer" and a "pretended moralist."

It was not for nothing that Mr. Wakley broke away with such violence from the trammels of professional precedence, and embarked in an enterprise which called for the most unbounded courage and the most enduring self-sacrifice. At the end of the first year of the publication of THE LANCET the young editor was able to say, "We have successfully resisted an attempt on the part of the three surgeons of St. Thomas's Hospital to gag the medical press. We have effected some modification of the recent law of the College of Surgeons, the effect of which is to destroy all competition between surgical teachers. We are glad to announce that, in respect of our efforts, a regulation has now been adopted at the hospitals in the Borough, by which clinical lectures both in Medicine and Surgery are to be delivered weekly, and the surgeons in passing through the wards will be required to make observations to the students in an audible voice upon every case of importance." After more than sixty-eight years it is hardly possible for medical students to realise what was meant by regulations of this kind. In his efforts Mr. Wakley was well aware that he would be assailed by much interested opposition, but, that notwithstanding, he declared he would faithfully and fearlessly discharge his duty. Mystery and ignorance were to him synonymous terms. The time, he declared, was come when ceremonies and signs had lost their charms; hieroglyphics and gilded serpents their power to deceive. This was the keystone of the edifice of reform he was destined in after years to construct—the motive power which enabled him so successfully to remove the cobwebs of tradition and ignorance which overhung and obscured the condition of the medical profession. He was not the man to put his hand to the plough and to look back, but against delusion, sham, and cant he maintained his stand, an unknown youth, teeth clenched, and face determined, fronting the world and anticipating his own future in it, with something of that feeling which, call it what we may, in the light of retrospection, has probably, by a divine law, filled every great and honest heart at the outset of a great career. The object for which he lived has been beautifully put by Professor Masson in speaking of another genius whose life had been spent in a similar fight:—

> Lay the vain impostors low,
> Blockheads fall in every foe,
> Splendour comes with every blow,
> Let me do or die.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The General Hospital.

THE election of Mr. Haslam as Surgeon to the General Hospital has given general satisfaction. It is felt that the traditions of the institution will be safe in his hands, and that the teaching strength will be considerably enhanced.

Christmas-time.

At most of the hospitals in the city there have been the usual festivities. The decorations have been in keeping with the season, and the generosity of the subscribers also. Whatever may be the feeling as to the propriety of keeping up the custom at the hospitals, and the necessary abstraction from other duties which it entails, no one having seen the happiness given to others, both young and old, who participate in the joyous proceedings, would grudge the efforts made to render the entertainments successful.

The New Coroner.

A suggestion of a useful kind has been made by the coroner for the city, Mr. O. Pemberton, that a society should be formed for visiting the homes of the poor and supplying fireguards when these are found to be absent. No doubt the number of cases of burns at this time of the year prompts the idea, which, however feasible in theory, might not be free from objection in practice on several grounds: the provision of such a precaution ought to be regarded as the duty of parents themselves, and might reasonably be insisted upon by precept or by a more forcible appeal.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Christmas Festivities to the Poor and in the Hospitals.

FOR years past it has been customary to give Christmas breakfasts and dinners to a large number of the deserving poor, this being effected by the liberal pecuniary donations of the rich, aided by contributions in kind from some generous tradesmen, who have contributed large quantities of tea, preserves, &c. A very large number of persons have thus been provided with a good breakfast or dinner, or both, and "the hungry have been filled with good things." The weather has been less severe—an agreeable change to the very old, the young, and indeed to all.

Jubilee of Mr. Henry Churton as Coroner for Chester District.

On Dec. 28th, 1841, Mr. Henry Churton, surgeon, was elected coroner for West Cheshire. On the corresponding day, 1891 (last Monday), he held two inquests at the Queen's Hotel, Park-entrance, Birkenhead. Advantage was taken by the foreman of the jury to offer their congratulations that he had been permitted to reach that memorable day, which was the jubilee of his coronership. They had always admired the faithful manner in which he had discharged the duties of his office, in the performance of which he neither coveted favour nor feared frown. They trusted that he would be spared to continue the faithful performance of his duties in the future as had been the case in the past. A member of the press present also congratulated Mr. Churton on the auspicious event, thanking him for the courtesy which he had always shown to the reporters in the discharge of their duties. In responding, Mr. Churton alluded with gratification to the fact that though Birkenhead had been incorporated as a borough and had its own court of quarter sessions, he had been appointed coroner to it as well as continuing in his office of county coroner. Mr. Churton is seventy-eight years of age, but in spite of this, and of a recent very severe illness, he enjoys excellent health, and was present at the funeral of his old friend, Mr. Clarke Aspinall, the late coroner for Liverpool, although the day was an extremely cold one. He then expressed to some of those present a hope that he might be able to discharge his duties up to the very last.

Theatres and Free Exits.

Boxing night has come and gone without any fatalities here. Before any theatre is licensed evidence must be given that it can, when filled, be emptied in a very few minutes. Moreover, the stage is now generally separated from the rest of the house by a fireproof curtain.

Dec. 29th, 1891.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Gateshead Calamity.

MOST of us in Newcastle heard for the first time on Sunday forenoon of the dreadful event which had taken place in the sister borough of Gateshead at the Theatre Royal on the preceding evening, and which resulted in the loss of ten lives. The story is very soon told; indeed, it is an old story: an alarm of fire, a panic, a rush down an ill-constructed gallery-stairs, where the sufferers fell, and were soon trampled to death or suffocated. An inquest is going on, but I do not think it can throw any additional light on the above statement of the event. Most of the medical men of Gateshead were on the spot to render all possible aid, but in proportion to the killed there were very few injured, and they were mostly sent to the Royal Infirmary, Newcastle, where they are doing well. Another of the injured has since died, making the eleventh victim of the disaster at the Theatre Royal, Gateshead.

Fire at Messrs. Atkinson and Philipson's Carriage Factory.

On Monday night last Newcastle was lit up with a lurid light which was seen to proceed from the direction of Messrs. Atkinson and Philipson's far-famed Northumberland coach works. It was soon evident that the whole place was in flames. The works are well known to most medical men in the northern counties. Fortunately no lives were lost, but the destruction of property was very great.

The Salt Water Supply at Tynemouth.

The *Newcastle Chronicle* has a good article on the system of salt water supply so long in use at Tynemouth, and which has proved such a blessing to the place and a comfort to the inhabitants. The system was introduced in 1875, under the then borough surveyor, Mr. J. P. Spencer. The pumps at the pumping station, of which there are two, are capable of each lifting 9000 gallons an hour. The water is raised to reservoirs and filter beds. The main reservoir is capable of holding 190,000 gallons, and is situated about a mile and a quarter from the pumps, with a rise of 150 feet. At present the town is intersected by about six miles of salt-water pipes. The water is laid on to private dwellings and public and private baths in the same manner as the ordinary town or potable water, and is supplied to householders at the very moderate rental of £1 per annum. The public baths are also supplied with salt water, and during the winter months these are in great demand. It is found, as regards street-watering, that the salt water keeps the roads and thoroughfares moist much longer than does the fresh. The salt water is likewise used for flushing the town sewers and latrines. It is pointed out in the article that for sixteen years the people of Tynemouth have adopted this practice, and, they believe, with excellent results, as they can point to a generally low death-rate; for instance, during the month of November last the average was 15·4, and for the four weeks ending Dec. 5th it was 19·9.

Darlington Hospital.

Dr. Simpson, who has been for some time house surgeon at the Darlington Hospital, has been presented with a purse of 30 guineas, of which £10 was voted by the committee and the rest subscribed by friends. The testimonial was accompanied with the regret of Dr. Simpson's friends at his leaving Darlington, and with best wishes for his success in his future career.

Tyne Port Sanitary Authority.

At the last meeting of the Tyne port sanitary authority it was reported that during the past two months visits had been made to 1358 British steamers and 342 sailing vessels, 321 foreign steamers and 203 sailing vessels, extra vessels 383, making a total of 2607 visits. At the same meeting the authority was asked to adopt a memorial which was about to be presented by Hull and Goole port sanitary authority to the Board of Trade, asking, amongst other matters, that the amount of space allowed to seamen be increased to 150 cubic feet, and compulsory provision of bath and lavatory accommodation be made. A spirited discussion took place on this subject, a member remarking that, compared with the time he was at sea, ships were now more like palaces, and that the air at sea was entirely different from what was to be had in towns. Dr. Armstrong, our able medical officer of health, however, re-

Digitized by Google

garded the proposal as an important one, and maintained that the air on board some small vessels was so bad that it could not be compared with anything on shore. In the end, the discussion was adjourned.

Influenza.

Influenza still continues rife in the north, and most practitioners are fully occupied. In the Cleveland district of North Yorkshire it is very bad. I have heard of a husband and wife lying dead together at New Marske after eight days' illness, and leaving four young children.

Cleveland Ambulance Centre.

The annual meeting of the Cleveland Centre of the St. John Ambulance Association was held recently at Middlesbrough. It was shown that the Association was doing excellent work, surrounded as the district is by mines and works where accidents occurred almost daily. During the year 818 persons had been instructed. Regretful allusion was made to the death of Dr. Duncan McCuaig, who had instructed the first class formed under this centre and five others of the fire brigade, also the borough police. Two thousand railway men had taken advantage of the concession of the North-Eastern Railway with regard to classes &c. The report dealt with other useful work done, and fully acknowledged the valuable assistance rendered by the honorary medical staff and other officials. Mr. Wayman Dixon, the honorary secretary of the district, may well be proud of his work.

Newcastle-on-Tyne, Dec. 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS)

Death of Mr. Imlach, F.R.C.S.Edin.

MR. FRANCIS B. IMLACH, F.R.C.S,Edin., died with painful suddenness when out of doors last week. He was walking along one of the most frequented streets in the city when he was observed to fall. He was taken to the infirmary directly, but was found to be dead. Mr. Imlach was born in 1829, and was a native of Edinburgh. He practised as a dentist and held a prominent position in that department. He took an active part in the management of various public bodies, and in none more so than the Royal Infirmary, of which he had for a number of years been one of the board of managers. Some years ago he occupied the presidential chair of the Royal College of Surgeons of Edinburgh. As a man he was much respected by the Fellows of both the Edinburgh Colleges; while his genial and sympathetic manner and kindly words were often valued, and were not infrequently a strength and encouragement to those to whom they were extended.

Professor McFadyean's Appointment.

Those who know Professor McFadyean, while gratified with his appointment to the Royal Veterinary College, London, are grieving over the prospect of losing him from the inner circle of more active workers in Edinburgh. Professor McFadyean, although he has devoted himself to veterinary science, is a graduate both in medicine and science of the University. No man in Edinburgh has a higher reputation amongst those who know him as an honest and reliable worker. And those who have had occasion to seek his assistance and help, know how ready and willing he always is to give them. His appointment to the London Veterinary College is the highest tribute that could be paid to the value of the work he has done in veterinary pathology.

Health of Edinburgh and Leith.

The mortality last week was 120, and the death-rate 24 per 1000. Diseases of the chest caused 69 deaths, and zymotic diseases 5. The intimations for the week were: typhoid fever, 3; diphtheria, 6; scarlatina, 14; measles, 13. In Leith the number of deaths last week was 31, making the death-rate 23 per 1000.

Health of Aberdeen.

In his report for the week ending Dec. 19th, Dr. Matthew Ray draws attention to the great prevalence of influenza in the city, and he makes some remarks upon its prevention and treatment. He says that in his practice as surgeon to the members of the police force he finds large doses of salicin to be followed by the best results. During the week the following cases of zymotic diseases were notified:—Scarlet fever, 31; typhoid fever, 1; whooping-cough, 45; and erysipelas, 10.

Influenza in Glasgow.

The presence of influenza is evidently making itself felt in Glasgow. During the past fortnight there were registered in the city 805 deaths, representing a death-rate of 31·7, in place of 27·5, in the previous fortnight. Of these deaths 365, or 46 per cent., were due to pulmonary diseases; to influenza, 39, as compared with 11 in the previous period. Four of these influenza fatalities took place in the Royal Lunatic Asylum, Gartnavel. These deaths from influenza also were distributed with fair uniformity over the city; their distribution as to age was:—Under one year, two; one to five years, six; twenty to twenty-nine years, one; thirty to thirty-nine years, two; forty to forty-nine years, three; fifty to fifty-nine years, seven; sixty years, and upwards, eighteen; no fatal case between five and twenty years; while 46 per cent. of those who died from influenza were over sixty. Only six were certified as due to influenza pure and simple, the remainder to complications such as pneumonia, bronchitis, and pleurisy. The whole bill of mortality therefore bears the impress of influenza. The number of deaths due to acute diseases of the lungs has risen 27 per cent.; the death-rate of persons under one year had increased only 6 per cent., while that of persons over sixty had increased 22 per cent. The above-noted increase of mortality is the more striking when it is stated that zymotic diseases had fallen both in number and mortality. Yet so mysterious is this disease in its ways, though a supplementary fever hospital (in Parliamentary-road) has been reopened for the special reception of cases of influenza as well as of measles and whooping cough, only four cases were in it on Nov. 30th. Of this supplementary hospital Dr. Wm. Gemmell has been appointed physician superintendent.

Victoria Infirmary, Glasgow.

At their annual meeting a few days ago the governors of this institution were able to submit a very favourable report. During the year 926 patients had received treatment, while at the dispensary for out-door patients 4744 consultations had taken place. The average residence of each in-door patient was 29·9 days. The total deaths numbered 72, or 8·3 per cent; deducting 20 cases (2·3 per cent.) in which the ailments or injuries were such that death occurred within forty-eight hours, the death-rate is reduced to 6 per cent. The cost of each fully occupied bed was £66 13*s.* 10*d.*, and the average cost per patient £5 5*s.* 4*d.* The total income exceeded the total expenditure by £2067 15*s.* 9*d.*; this sum has been transferred to capital account, which now amounts to £12,283 1*s.* 3*d.* It is satisfactory to note that of the sums received nearly £1000, or about a fourth of the ordinary income, has been contributed by workmen themselves. The infirmary is at present undergoing extension, another pavilion being added to it, which will raise its accommodation to 150 beds. A "nurses' home" is also nearing completion, providing a separate bedroom for each nurse, and a large common sitting or recreation-room. This home is to be furnished, at a cost of £500, by Mr. and Mrs. Renny Watson in commemoration of their silver wedding. The governing body of this infirmary is peculiar in this respect, that it includes three direct representatives of the contributing workmen. The privilege of sending these three governors is one highly prized by the working men, as furnishing a guarantee that their interests will be attended to. It is specially stated in the governors' report that the representatives hitherto elected by the workmen "have been of great practical service" Owing to the disappearance of some of the small burghs round Glasgow, which have now been merged in the city proper, certain alterations have to be made in the board of governors; three additional governors will be elected by the General Court of Contributors, and one additional representative will be elected by the workmen.

The medical classes in Edinburgh reopen on Tuesday, Jan. 5th.

The Aberdeen Medico-Chirurgical Society held its annual

Digitized by Google

dinner in the Society's hall on Dec. 15th, and there was a large attendance. In the unavoidable absence of the president, Dr. Garden, the chair was occupied by Dr. Angus Fraser, and Dr. Edmond acted as croupier.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Dr. Edward J. O'Neill of Dublin.

DR. O'NEILL died last week at his residence, 6, Cavendish-row, Dublin, from typhoid fever, aged fifty-five years. Deceased obtained the M.D. of St. Andrews in 1858, and the licence in surgery of the Royal College of Surgeons in Ireland five years previously. He was a Director of the Apothecaries' Hall.

Trinity College Tercentenary, 1892.

A committee has been appointed by the Tercentenary Committee to provide for the reception of guests at the tercentenary celebration, and includes the names of Sir George Porter, Bart., the President of the Royal College of Physicians, Dr. Cruise, Sir John Banks, &c. The celebration will last from Tuesday, July 5th, to the following Friday, and will consist of a commemoration service at St. Patrick's Cathedral, the presentation of congratulatory addresses by delegates from various universities, and the conferring of honorary degrees on a number of distinguished visitors. There will also be a banquet and garden parties, the college races, and a ball. A play also will be performed in the Gaiety Theatre by students and graduates of the University.

Kilkenny District Lunatic Asylum.

Thirteen of the governors of the Kilkenny Asylum having resigned in consequence of the Board of Control having, contrary to their wish, expended a sum of money for the purchase of additional land to the asylum, the Under-Secretary has, in a lengthened letter, explained the action of the Board of Control. There were until recently only twenty-eight acres for over 300 inmates, and for some time past those who inspected the asylum strongly urged the absolute necessity of obtaining more land. In the last report issued it is stated that the asylum, containing more than 300 patients, has only about eight acres available for tillage attached to it. This has been brought under the consideration of the governors; but as yet they refuse to add to the estate, stating that the amount of land is sufficient; yet the resident medical superintendent reports that if the farm were of sufficient size he would be able to nearly double the number of male patients engaged in agriculture. Some adjacent land being about to be sold, the Board of Control recommended that the governors should purchase it; but as they declined, the ground in question was purchased by the Board. The governors regarded this as arbitrary, and accordingly the majority resigned. It must also not be forgotten that the duty of seeing that a lunatic asylum is properly provided with land is imposed by law on the Board of Control. A special meeting of the governors of Kilkenny Asylum will shortly be held to consider the letter of the Under-Secretary in reference to the dispute between the governors and the Board of Control.

Cork Hospital Saturday.

The amount at the disposal of the committee, after defraying all expenses, for distribution to the various hospitals will be something over £600.

A woman named Stretton died recently at Tralee, aged 108 years, and on the same day a woman named Moriarty died at Barrow at the age of 104.

Dec. 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Mercury, Syphilis, and Tabes Dorsalis.

THE literature of that interesting clinical discussion, the supposed or pretended connexion between syphilis and its mercurial treatment on the one hand and locomotor ataxia on the other, received a fresh contribution from that eminent syphilographer, M. Fournier, at a recent meeting of the Academy of Medicine. Two reasons, he said, determined his undertaking this inquiry: First, the supervention of tabes in two of his patients in spite of a rational, regular, and sustained course of antisyphilitic treatment; and secondly, the necessity of judging at its proper value the accusation brought forward against the mercurial method of being a cause of tabes in syphilitic subjects. In proof of this the deleterious action of mercury, when abused, on the vessels and vascular endothelium was advanced, whence it was concluded that degeneration or sclerotic changes in various tissues, amongst them the nervous, were possible, and hence tabes dorsalis. M. Fournier's inquiries into this gravely important question extended over 321 cases of locomotor ataxia in syphilitics. As a result of his analysis of their cases he concludes that mercury must be put *hors de cause:* First, because amongst these 321 cases twenty-four became tabetic without having ever had mercury administered to them in any shape: and, secondly, because he is able to show conclusively that the number of syphilitic subjects who develop tabes is in increased ratio to the length of time mercurial treatment was carried on. For instance, amongst twenty-three syphilitics subjected to mercurial courses who developed tabes he found that no fewer than twenty-two were treated for various terms of less than one year, while only one developed disease of the posterior columns after a mercurial course lasting from two to four years.

Functions of the Thyroid Gland.

At a late meeting of the Biological Society M. Gley recorded the results of some experimental observations he had made on the thyroid. Removal of this gland was followed by death in the rabbit and dog. He found, however, that this was not the case if two small accessory glandules situated on each side below the main structure were left. These soon developed, and took on apparently the function of the entire gland as before. He referred also to the apparent connexion as to function that exists between the thyroid and pituitary bodies, and demonstrated the trophic *rôle* which the latter structure plays in the rabbit and the dog. He showed a dog in which he had removed the thyroid entirely, but which had survived to cicatrisation by means of intravenous injections of an extract from the tissues of the glands. Later on the animal showed signs of trophic troubles analogous to those which supervene on the removal of the pituitary body.

Ocular Troubles in Influenza.

M. Galezowski records that as a result or complication of influenza he frequently found spasm of the arteries of the retina. This spasm was manifested by a passing sensation of dazzling, and by an amblyopia which lasted from a few hours to some days. Examination of the fundus revealed the branches of the central artery of the retina contracted and almost effaced from view. He concludes that the amblyopia was purely dynamic, and was perhaps due to some toxic substance secreted by the microbe of this singular disease acting on the vaso-motor nerves. Sulphate of quinine generally relieved the condition.

Unusual Foreign Body in the Rectum.

At the Surgical Society M. Marchand showed a wine-glass which he had extracted from the rectum of an individual seventeen hours after its introduction. After several ineffectual attempts to get it away through the anus, he found it necessary to incise the posterior wall of the rectum and perineum. The operation was quite successful, for fifteen days after the suturing of the bowel the patient was discharged with a sphincter perfectly reconstituted.

Recurrent Erysipelas: its Pathogenesis.

This curious ailment was the subject of discussion at the Société Médical des Hôpitaux on Dec. 18th, a paper contributed by MM. Hirtz and Vidal being of special interest. The basis of these observers' communication was the case of a barge woman, aged thirty-three, who was wrecked four years ago, and in whom menstruation, up to that time regular, has not reappeared. Four months after her rescue she suffered from a first attack of facial erysipelas, the invasion of which was marked by a rigor, and which, involving the scalp, was accompanied by severe general symptoms. The attack terminated on the

Digitized by Google

ninth day, and was attended by loss of hair. A week later the disease reappeared on the face. During a sojourn of four months at the Hôpital Necker the patient had two relapses. It is to be noted that neither the foregoing nor any subsequent seizure coincided with what should have been the menstrual period. Up to her admission in December, 1890, into the Hôpital Cochin only once had she been free from an attack for two consecutive months, the erysipelas often relapsing several times a month. She entered that hospital to be treated, not for erysipelas, but for Bright's disease, the symptoms being general œdema of the face and limbs, copious epistaxes, dimness of vision, a well-marked *bruit de galop* (reduplication of the first sound), and albuminuria (1 or 2 grammes of albumen per litre). Between Dec. 24th, 1890, and March 31st, 1891, she suffered from at least twenty attacks of erysipelas, the part affected being now the face, now the upper and inner surface of the thighs. In the latter case the blush always radiated from patches of eczema similarly situated. The attacks were always mild, the temperature rarely reaching 100·4° F., and the duration being variable, and often not exceeding a few hours. On April 14th, however, there occurred a fresh attack, characterised by violent rigors, high fever (104·9° F.) persisting for a week, great disfigurement of the features and scalp (large phlyctenulæ developing at those situations), together with disquieting adynamic symptoms. On the tenth day the temperature fell to the normal point, and convalescence set in. In the course of the succeeding month she had three mild apyretic attacks of brief duration. Pure cultures of *streptococcus* were procured from specimens of blood taken respectively during a mild attack on March 26th and during the severe attack above mentioned. The March culture inoculated into the ears of two rabbits gave rise in the one to the most violent experimental erysipelas ever witnessed by MM. Hirtz and Vidal. The local infiltration was enormous, and the temperature rose to 106·7° F. In the other rabbit death supervened in forty-eight hours. There was discovered post mortem splenisation of the lungs and dessemination of the streptococcus in all the viscera. The absence of synchronism between the suppressed menstrual periods and the accesses of erysipelas is a noteworthy circumstance in this case. Instances of vicarious monthly attacks of facial erysipelas occurring during the menopause are not infrequent. The authors of the paper under consideration cite an example in a woman of fifty. The occurrence of nephritis after four years of recurrent erysipelas is a proof that sometimes, at any rate, the albuminuria attending erysipelas may become permanent. Dr. Pye-Smith, in his classical work,[1] states that this is a very rare event. The presence of *portes d'entrée* to the streptococcus in the guise of eczematous patches on the thighs (and in the case cited of menopausal erysipelas of a similar patch on the ear) lends support to the now generally accepted assertion of Trousseau that a local lesion of some kind is always demonstrable in these cases if a careful search be made. The case also teaches us that, however mild the majority of such attacks may be, the onset of a serious one is to be apprehended. In the course of the discussion raised by the reading of the above paper, M. Labbé expressed doubt as to the authenticity of so-called menstrual erysipelas, believing that it is really only erythema. This view was strongly combated by MM. Guyot and Rendu. The latter physician reminded the Society that, when the view now advanced by M. Labbé was some years ago promulgated by the late Maurice Raynaud, the Society rejected it by an overwhelming majority. M. Rendu remembers well how erysipelas in a severe form was once communicated at the Hôpital St. Louis to a neighbouring patient by a woman who was suffering from one of these trifling apyretic attacks.

Dec. 29th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Influenza.

THE Medical Department in the Prussian War Office has published a book on the influenza epidemic of 1889–90 in the German army. The number of cases was 8778, and the epidemic spread from north-east to south-west. The book contains highly convincing proofs of the infectious character of the disease. It is copiously illustrated, and treats also of the causes, treatment, and prophylaxis of the disease. On Dec. 17th Prof. Nothnagel of Vienna lectured to his students on influenza. After expatiating on the history of influenza and its dissemination this year, he continued as follows: "The following questions of general interest arise. How far is one protected in influenza against relapses? Does one attack confer immunity or not? Does it leave the patient more predisposed for a second attack or less? From the observations hitherto made one may say that one attack does not increase the predisposition; whether it diminishes it will perhaps now appear; but here, too, one must say, 'Non liquet.' One thing is clear—influenza is an infectious disease. Despite all bacteriological investigations, the specific agent of infection has not yet been discovered. In short, in spite of all descriptions and investigations, we have a great chaos before us, but no clearness. One thing is beyond doubt: influenza may certainly be miasmatic, for it was observed that the epidemic spread at a rate much more rapid than that of human intercourse. As regards the symptoms, we adhere to the old classification, and distinguish between nervous, gastric, and catarrhal influenza. The virus of influenza shares with many other microbes the quality that it infects and affects the whole body; the most various parts of the frame may suffer from it. It has struck observers from of old that the fatal cases of influenza are mostly those in which the organs of respiration are affected. Slight croupy pneumonia may occur in influenza and along with it. Apart from this, however, there is a genuine influenza pneumonia which, owing to its severe effect on the heart, is more dangerous than bronchial pneumonia. The prognosis is very various. Weak persons and those who suffer from heart disease or tuberculosis seem to be exposed to greater dangers than others." In conclusion, Professor Nothnagel spoke of the treatment of the disease, declaring that there is no specific against it, and that the treatment must be symptomatic, and most decidedly warning against all experiments with antipyrin and antifebrin. In the week which ended on Dec. 12th the number of deaths in Berlin from influenza was eighty.

Rifle-shot Wounds.

In a recent lecture the celebrated surgeon Professor von Bardeleben stated that wounds inflicted by the new rifle bullets are simple round holes. He reported on two wounds caused by the firing of sentinels. In one case the bullet had gone through the knee-joint of a man, and the wound healed so completely that the mobility of the joint was unimpaired. In the other case the bullet struck a young lady in the thigh without striking a bone. The only treatment was the application of an antiseptic bandage, and when the bandage was removed the wound was completely healed.

Death of Dr. Ignaz Hirschler.

Dr. Ignaz Hirschler, the pioneer of modern ophthalmology in Hungary, died the other day at Pesth. He was born at Pressburg in 1823, and studied medicine in Vienna. After having been for some time assistant to a distinguished ophthalmologist there, named Anton von Rosas, he went to Paris, where he studied under Desmarres. In the clinic of that physician, then the gathering-place of ophthalmologists from all parts of the civilised world, he met Albrecht von Graefe, to whom, with Helmholtz and Donders, the world mainly owes the enormous progress which has since been made in ophthalmology. In 1849 Hirschler returned to Hungary, and established himself in Pesth. For a long time he was the only ophthalmic surgeon in Hungary. He published most of the results of his observations in Graefe's *Archiv*. Among the most important of his writings are those on cysticercus in the anterior chamber of the eye, disturbances of vision due to alcohol and tobacco, and pigmentation of the cornea. Though not an official teacher in any university, he gave courses of private lectures on ophthalmology, which his position in a hospital enabled him amply to illustrate. He also took part from time to time in political life.

The Virchow Jubilee.

The financial surplus of the Virchow Jubilee amounts to 23,550 marks. Twenty thousand were saved by the Festal Committee from the proceeds of the great collection, and the remaining 3550 are the publishers' payments for the

[1] Practice of Medicine, vol. i., p. 254.

Digitized by Google

contriontions to the festal work, the collaborators of which friends and former assistants of Virchow preferred in this case to work without reward. The whole surplus has been added to the Rudolf Virchow Fund for the support of scientific investigations, which amounted before this addition to 97,000 marks. Some thousands, it is true, will have to be refunded, for the Festal Committee has resolved, with Virchow's consent, to distribute bronze casts of the Virchow medal to the most eminent European pathological anatomists and to the corporations which took part in the jubilee.

Professor Graefe.

Professor Graefe, a cousin and very distinguished pupil of the famous founder of modern ophthalmology, Albrecht von Graefe, has resigned his office as head of the eye clinic of the University of Halle.

Dr. Paul Michelson, of the University of Königsberg, died two or three days before Christmas.

On the occasion of the fiftieth anniversary of Professor Bardeleben's graduation, the Emperor conferred on him the distinction of hereditary nobility.

Professor Billroth is suffering from influenza.

Owing to the prevalence of yellow fever in Brazil, and especially in Santos, all ships arriving at Hamburg from there have to be disinfected.

Berlin, Dec. 29th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Prophylactic Measures to Prevent Cholera.

IN view of the International Quarantine Commission so soon to take place at Venice, it will be interesting to note what Egypt did to guard herself against any possible outbreak of cholera during the summer of 1891. The disease broke out in Mecca in July, and was also known to be lurking in Syria, so that Egypt seemed menaced from two points. During the months of August and September 11,950 returning pilgrims were received at the quarantine station of El Tor; themselves and their clothing were thoroughly washed and disinfected, and though 121 deaths occurred among them, only six were victims to cholera. It is most satisfactory to note that no cholera appeared in the track of these pilgrims, though the disease broke out again in Syria shortly after their return there. Some 450 pilgrims, mostly camel drivers, returned to Egypt by the land route, and, as usual, arrived in good health. In Egypt itself strict measures were taken to enforce an amount of cleanliness, which is unhappily habitually absent from this country. Responsible committees were formed in all the chief towns to inspect nuisances and insist upon sanitary reforms. All worked with a will, except the representatives of the Wakfs, the Ecclesiastical Department, who do their utmost to obstruct real progress. The following list will give an idea of what was done during the summer months, and it is to be hoped that the Government may in the future be induced to carry out a similar "spring cleaning" every year. Some 13,000 Cairo huts were cleansed and whitewashed, besides an equal number in the provincial towns, while more than 3000 of the worst of them were destroyed; 2000 more were condemned, but have not yet been demolished; 1700 small inns, half of which were in Alexandria, have been cleansed and whitewashed, and 700 others were condemned and closed; 220 of the public baths were shut up, and 710 others were well cleaned. Nearly 4000 mosques were forced to have their latrines cleansed and whitewashed, but there remained 1800, mostly in the country towns, where sufficient sanitation was not carried out; 629 drains leading directly into drinking water canals were peremptorily closed, but the Commission reported that there remained 113 drains in Behera province to be so treated, and 79 more in Guergeh province. 7514 of the low-class stables and shops were treated with whitewash, and 642 public kitchens were overhauled, while in Cairo alone 1719 tripe shops were compulsorily made clean. Rags and bone warehouses were banished to the outskirts of towns. 14,643 private houses of the lower classes were whitewashed in Cairo alone, besides 13,540 of the small shops and coffee houses.

Sanitary Department

Brigade-Surgeon Green Pasha has been compelled to resign his post as director of the sanitary services in consequence of incurable deafness. He is fortunate in having enlisted under old pension rules, which entitle him to a life allowance of £650 a year after only seven years' service. By the existing rules he would be entitled only to a bonus of £700 and no yearly pension. The higher officials of the department presented him with a gold and silver coffee-service and tray as a mark of sympathy with his physical affliction. Surgeon-Major Rogers Pasha, his successor, has for the last eight years been the principal medical officer of the Egyptian Army.

Influenza reimported from Europe.

At the end of October last an English steamer arrived at Alexandria having on board some passengers who had just left influenza-stricken friends in Spain. Two families became ill on board, and carried the disease ashore with them, so that several cases occurred during November in Alexandria, Mansourah, and Cairo. The patients are chiefly confined to the families of those who had travelled on this steamer, and the disease has shown no tendency to spread universally.

Government Hospital at Alexandria.

This hospital continues to improve, and the new out-patient department is now attended by 200 natives every day, who testify to its popularity. His Highness the Khedive recently visited it in order to inaugurate a small mosque chapel which has just been completed for the use of the in-patients. The experiments upon lepers with Koch's tuberculin have now been discontinued, for though there was perhaps a very slight improvement in some cases, there was not sufficient to encourage either doctor or patient.

Cairo Medical School.

The only medical school in Egypt is about to lose its director, whose resignation has been demanded by the Government in consequence of some late intrigues among the native professors and insubordinate conduct on the part of the principal. He was removed in 1884 from the control of the Quarantine Service, and in 1885 from the Sanitary Department for various irregularities. He is to be succeeded by Dr. Ibrahim Pacha Hassan as director, and by Dr. Keatinge as vice-director. Dr. Keatinge was one of the English medical officers attached to the Egyptian Army for six years, and now for more than a year has been professor of anatomy in the medical school. His new appointment will give him fresh opportunities for continuing the good work which he has already begun.

Cairo, Dec. 7th.

Obituary.

SIR J. RISDON BENNETT, M.D., F.R.C.P.

JAMES RISDON BENNETT was the son of the Rev. Dr. Bennett, a learned Nonconformist divine, and was descended through his mother from Risdon Daricott, a man of great piety and worth, who is mentioned in the "Dictionary of National Biography." After choosing the medical profession he was apprenticed to the late Mr. Thomas of Sheffield, and afterwards studied at Edinburgh, where he took his degree in 1833, and soon after went abroad as travelling physician to one of the Earl of Aberdeen's sons. He spent some time at Rome, and became acquainted with French, Italian, and German. After his return to England he was for a time connected with Charing-cross Hospital, but soon afterwards was appointed assistant physician to St. Thomas's, then and for many years afterwards in the place where it was founded, in the borough of Southwark. Subsequently he joined the new Hospital for Diseases of the Chest at Victoria-park and became an accomplished auscultator. During the greater part of his professional life Dr. Bennett lived in Finsbury-square, near his friend and neighbour, the late Dr. Jeaffreson of St. Bartholomew's Hospital, Dr. Peacock, his colleague at St. Thomas's, Dr. Gull of Guy's, and Dr. Herbert Davies of the London Hospital.

Digitized by Google

Here he had a good City practice for many years. Here he brought up his family, and here he sustained a severe bereavement in the loss of his eldest son, a barrister of great promise. He moved to Cavendish-square in 1876, the year in which he was elected President of the College of Physicians in succession to the late Dr. Alderson. He filled this high office during five years with characteristic dignity and judgment. He had previously served several offices at the College with credit, and had delivered the Croonian Lectures on Bronchitis in 1863, and the Lumleian Lectures on Intra-thoracic Tumours in 1870. After he had retired from the chair he continued to be a constant attendant at the comitia, and occasionally spoke with clear, good sense and apt expression, equally free from the heat of youth and the captiousness of old age.

He took an active part as chairman of the Organising Committee in preparing for the International Congress of 1881, and at the first general meeting at St. James's Hall welcomed the assembly in a well-worded and well-delivered French speech. In his later years Sir Risdon Bennett's opinion was frequently sought by Government, and he was well known in the City as a consultant in cases of life insurance. It was much regretted at the time that he was not put on the Royal Commission which dealt with the proposed University in and for London; the marked absence of any member of the medical profession on that Commission was justly resented, and Sir R. Bennett's great experience, impartiality, and judgment would perhaps have prevented the divided report which has led to the present unsettled state of the question. At the advanced age of eighty-two Sir R. Bennett had still full possession of his faculties and a considerable share of bodily strength. He went safely through a sharp attack of influenza last spring; and those who attended the Section of Medicine at the meeting of the British Medical Association last July at Bournemouth will remember how vigorously, tersely, and genially he took part in one of the debates. Soon after, however, his memory of words began to fail, and, early in October, he consulted a medical friend on the subject, stating the symptoms with his usual clearness and appreciation, and bringing a prescription which he had failed in writing as evidence of the degree of agraphia as well as aphasia. From that time he passed, by gentle and painless gradations of decay, to the closing scene. His funeral at the King's Weighhouse Chapel was attended by the President, Treasurer, and censors of the College of Physicians, by the senior physicians of the chief hospitals, and by many other professional friends; while other contemporary and attached colleagues were only prevented being present by the infirmities of advanced age. Sir Risdon Bennett was tall, with a grave and dignified aspect and a pleasant smile, a courteous and hospitable host, a good talker, but content to take his share in conversation; excellent on a committee, sagacious in consultation. He was scrupulously exact and honourable in all the relations of life; and, while far from anything like cant, maintained in practice as well as in profession the high standard of Christian conviction. He published little, his Lumleian lectures and a few contributions to the medical societies being almost the whole of his printed works: but he occasionally wrote slighter papers, the last of which was an interesting memoir of the private and religious life of the great Haller. He left three sons and three daughters; one only, Dr. Selfe Bennett, follows his father's profession. He had so long left his hospital that he was scarcely known to any except the senior members of the staff; but at the College of Physicians and among many of the oldest and most honoured of the profession his good company, his *mitis sapientia*, and his staunch friendship will long be remembered with affectionate regret.

THE SERVICES.

Surgeon-Lieutenant-Colonel J. G. Rogers, Army Medical Staff, who has been Principal Medical Officer of the Egyptian Military Forces since November, 1883, is, we learn, about to vacate that position, having been offered by the Khedive the appointment of Director-General of the Board of Health.

ARMY MEDICAL STAFF.—Brigade-Surgeon-Lieutenant-Colonel John Butler Hamilton, M.D., to be Surgeon-Colonel, vice E. G. McDowell, C.B., retired, and Surgeon-Lieutenant-Colonel George Joseph Hamilton Evatt, M.D., to be Brigade-Surgeon-Lieutenant-Colonel, vice J. B. Hamilton, M.D (both dated Nov. 30th, 1891); Surgeon-Major-General D. A. C Fraser, M.D., having attained the age of sixty, has been placed on retired pay.

ARMY MEDICAL RESERVE OF OFFICERS.—The surname of Surgeon F. St. J. Kemm, 3rd Volunteer Battalion, the Prince Albert's (Somersetshire Light Infantry), is as above, and not as stated in the *Gazette* of Dec. 1st, 1891.

VOLUNTEER CORPS.—*Artillery:* 1st Cumberland: Surgeon-Captain J. A. Macdougall to be Surgeon-Major (dated Dec. 30th, 1891).—1st Devonshire (Western Division, Royal Artillery): Arthur Goulston, Gent., to be Surgeon-Lieutenant (dated Dec. 30th, 1891).—*Rifle:* 2nd Volunteer Battalion, the East Lancashire Regiment: Surgeon-Lieutenant-Colonel L. Fisher, M D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated Dec 30th, 1891).

Medical News.

UNIVERSITY OF LONDON.—The following gentlemen have passed the examination for Honours at the recent B S. examination:—

First Class.—George Francis Blacker (Scholarship and Gold Medal), University College; Herbert Geo. Graham Cook (Gold Medal), St. Bartholomew's Hospital; John Lloyd Roberts, M.D., B.A., B.Sc., Guy's Hospital; Ransom Pickard, St. Bartholomew's Hospital, and Wm. Gusterson Rogers, Guy's Hospital (equal).

Second Class.—William McAdam Eccles, St. Bartholomew's Hospital; Thomas Benjamin Philip Davies, Guy's Hospital; Robert Henry Elliot and Holburt J. Waring, B.Sc., St. Bartholomew's Hospital (equal); Thomas Philip Cowen, St. Thomas's Hospital, and Harold Hodgson, Guy's Hospital (equal).

Third Class.—John Edward Platt, M.D., Owens College and Manchester Royal Infirmary; Alfred Theodore Rake and Arthur Stanley Wohlmann, Guy's Hospital (equal); Harold Meredith Richards, University College.

UNIVERSITY OF OXFORD.—In a congregation held on the 17th ult. the degree of D. Med. was conferred on

Henry John Tylden, Exeter.

UNIVERSITY OF DUBLIN.—At a meeting of the Senate recently the following degrees were conferred:—

Bachelor in Obstetrics.—Abraham W. Bate.

Bachelor in Surgery.—Dionysius Lionel Fitzgerald.

Bachelor in Medicine.—Abraham William Bate, John Simpson Jackson, Frederick Edward Rainsford.

Bachelor in Medicine, Surgery, and Obstetrics.—Bernard Robert Chatterton, Patrick Bernard Considine, Henry Croly, Alfred John Davoren, Raymond Alexander Dowdall, James Augustine Haran, Frederick William Kennedy, Patrick Percy Kilkelly, Joseph John Long, Michael Archdale Morris, Cecil Orpin, Victor John Rutledge, William Arthur Valentine, William Arthur Winter.

In absentii.—Rev. Kenneth William Stewart (stip. cond.).

Doctor in Medicine.—Edward Litton Luther, Samuel Wm. Robinson.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the December sittings of the examiners in Public Health, the following gentlemen were admitted diplomates in Public Health:—

John Alexander, M.D., Wick.
Francis Hollingsworth May, L.R.C.P., Birmingham.

SOCIETY OF APOTHECARIES OF LONDON.—EXAMINATION IN ARTS.—The following have passed in all the subjects required for registration:—

First Class (in order of merit).—F. C. Blakiston, E. S. Crispin, J. C. Hollocombe, B. H. E. Evans.

Second Class (in alphabetical order).—M. C. B. Anderson, H. L. Apthorp, A. Atherton, C. E. Carter, M. S. Coghill, G. E. Duncan, W. R. Field, A. H. Gadsden, J P. E. Henery, B. Hogan, J. B. B. Howat, T. W. Hyde, E. Joseph, L. F. Leslie, H. R. Marsh, H. R. Miller, J. Milligan, P. D. Pywell, A. L. Rozelaar, F. S. Vine, H. J. Walker, F. E. Wayte, E. M. Wells, R. G. Whiting.

WOLVERHAMPTON INFECTIOUS DISEASES HOSPITAL. The new buildings at the Borough Hospital for Infectious Diseases, Green-lane, Wolverhampton, were formally opened on Wednesday by Alderman Major, the chairman of the Sanitary Committee, in the presence of a number of members of the Town Council and corporation officials. The additions which have been made to the hospital comprise an entrance-lodge, enlargement of the administrative block, and a hospital pavilion.

Digitized by Google

TRAFFICKING IN DEAD BODIES.—At the Glasgow High Court on the 21st ult., John Daniel was charged with a contravention of the Anatomy Act by delivering bodies from the Glasgow City Poor-house for dissection without the certificate required by the Act. After a long trial the judge imposed a sentence of fourteen days' imprisonment. It was stated that Daniel pretended to take the bodies away for burial, but removed them instead to the dissecting house, receiving a fee for each.

LEEDS IMPROVEMENT BILL.—In addition to providing further hospital accommodation, whether temporary or permanent, for the treatment and isolation of persons suffering from infectious diseases, the Corporation desire to make further provisions as to the removal and burial of dead bodies, for preventing the letting of infected premises, for the disinfection of refuse, for cleansing and disinfecting bedding, clothing, and premises, with power of entry, for which purposes the Infectious Diseases Notification Act (1889) and the Infectious Diseases Prevention Act (1890) are incorporated.

THE KILMARNOCK INFIRMARY.—Great activity has prevailed in the several departments of this institution, during the past year. The number of cases treated was considerably above the previous year, and the financial prospects show an improvement. In the annual report for 1890 reference was made to the generosity of the Dowager Lady Scott Howard de Walden to build an important addition to the infirmary, the chief features of which are a handsome children's ward, dormitories for nine nurses, and new domestic offices: also new laboratory arrangements both for the new extension and the old edifice. Three ladies in the district have contributed £1000 each for the purpose of endowing cots. A hearty response was made by the working classes to the request of the directors for additional financial aid, which has already, to some extent, been carried out. The capital account amounted to £10,105.

PRESENTATIONS.—Dr. Henry White, of Manningham-lane, Bradford, the honorary instructor of the two ambulance classes composed of employés in the service of the Midland Railway Company at Manningham, and under the auspices of the St. John Ambulance Association and the patronage of the railway company, has been presented with an elegant oaken cigar chest, well stocked with cigars, by the members of the classes in appreciation of his painstaking and efficient instruction on first aid ambulance work. —Mr. A. W. Stocks, M.R.C.S., has received a presentation from the honorary medical staff of the Salford Royal Hospital on the occasion of his resigning the office of honorary surgeon after a prolonged service of thirty-five years devoted to the institution, and the unique position he had occupied for upwards of twenty years as senior honorary surgeon and chairman of the medical board.

ROYAL INSTITUTION.—A course of six lectures on "Life in Motion," adapted to a juvenile audience, was commenced on Tuesday, Dec. 29th, by John G. McKendrick, M.D., LL.D., F.R.S., Professor of Physiology in the University of Glasgow. The lecture, which was introductory in character, dealt with the movements characteristic of living beings. Various interesting demonstrations were made of the action of muscular tissue and the electrical stimulation to contraction through the nerves, and also to the muscle direct. The production of tetanus or spasm was clearly shown by a very delicate instrument sent direct from Berlin. The experiments were all very satisfactory, and delighted and instructed not only the juveniles present, who occupied the front benches, but also the adult part of the audience, which entirely filled the rest of the theatre. The subject was resumed on Thursday, and the lectures are to be delivered every alternate day till the end of next week.

Saturday, January 9.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

ROYAL INSTITUTION.—3 P.M. Professor John G. McKendrick: Life in Motion, or the Animal Machine.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

THE LANCET DURING 1891.

THE following particulars of the work of THE LANCET during the past year have been forwarded to us from a correspondent; and as they are likely to prove of interest to our readers we, after categorically verifying the accuracy of the figures, publish them. From the figures submitted it appears that in the year 1887 THE LANCET contained 11,744 columns, in 1888 it contained 12,376, in 1889 it rose to 13,728 columns, and in 1890 the figure reached was 14,032 columns. The year 1891 shows a still higher figure, a total of 14,304 columns, 5980 of which were devoted to purely literary matters, 8324 columns contained advertisements, and space amounting to nearly 150 columns was required for the purpose of an index. From these figures a simple calculation will show that the average size of each weekly impression has amounted to 137 pages. Looking at the impressions individually it will be found that two of the numbers contain 200 pages each—namely, those of January 1st and September 5th. No single number of THE LANCET of corresponding size has ever before been offered to the subscribers. Of the other numbers there were three of 152 pages, two of 144 pages, thirty-three of 136 pages, ten of 128 pages, and two of 120 pages. THE LANCET last year was permanently enlarged to 112 pages, but that figure has been exceeded by every number issued during the year 1891. One very marked feature in THE LANCET for 1891 was the publication of two Special Supplements in aid of the

Digitized by Google

Metropolitan Hospital Sunday Fund, the second of which contained a selection of sermons preached in aid of this fund. Another Supplement (following up and detailing the results of the Special Supplement of the previous year devoted to these subjects) dealt with life assurance and the medical profession. The columns of literary matter include reports of clinical lectures extending over 583 columns; nearly 846 were devoted to Clinical Notes, and about 590 to Original Articles. The department of the Mirror of Hospital Practice occupies over 310 columns, and no less than 208 have this year been devoted to Analytical Articles and Pharmacology. Leading Articles and Annotations have taken up about 905 columns, and 190 were devoted to Critical Reviews of Books bearing on Medical Science. The Correspondence columns exceed 511, and Articles on the Public Health to the extent of 215 columns have been printed. The Reports of the General Medical Council extended to 47 columns; of the Meeting of the British Medical Association to 35 columns, and a Special and Full Report of the International Congress of Hygiene occupied nearly 400 columns of THE LANCET. Matter to the extent of 5394 columns has thus been accounted for, the remaining 586 columns having been devoted to Obituary Notices, Miscellaneous Medical News, Law Reports on Medical Questions, and Parliamentary News, of Interest to the Profession.

A Subscriber.—The question is more legal than medical. But we will not shrink from giving our opinion. We do not quite agree with our correspondent. The other party was acting for him, and he has undergone a very serious ordeal of suffering and injury—which he certainly never bargained for in undertaking, as he did kindly, to officiate for a friend. The three facts mentioned do not, it seems to us, alter the case. The acceptance of responsibility for the full payment may involve inconvenience and hardship to our correspondent, but it will give him lasting satisfaction. It is one thing to ask a friend to undertake the duty of a *locum tenens*, and another to hold him responsible for all legal consequences.

Professor Middendorp.—The copy of the monograph has not been received.

Mr. B. H. N. (Gijon).—We do not give medical advice.

"CURRENT FROM THE MAIN."

To the Editors of THE LANCET.

SIRS,—With reference to my communication in THE LANCET of the 19th ult., I find that it would have been more in accordance with what is occurring in actual practice at the present time to have instanced the supposed incandescent lamp as requiring about 60 watts instead of 50. This does not affect the conclusions arrived at, as even 600 milliampères is still within the safety limit under the conditions named. I am, Sirs, yours faithfully,

Brighton, Dec. 29th, 1891. W. S. HEDLEY, M.D.

AN EIGHTEENTH-CENTURY POET'S PRECEPTS FOR THE MAINTENANCE OF GOOD HEALTH.

PREVENTION is better than cure, and it may be worth while to transcribe some good hygienic rules, formulated by Monsieur l'Abbé de Grecourt, in his work published in 1772. They run as follows:—

USANE INFALLIBLE CONTRE TOUTES SORTES DE MALADIES.

Prenez deux grains d'indifférence,
Autant de résolution,
Dont vous ferez infusion
Avec du suc de patience.
Point de procès, point de querelle,
D'ambition, point de faux zèle,
Demi-livre de gaieté,
Deux onces de société,
Avec deux dragmes d'exercise:
Point de femme, point d'avarice,
Un bon grain de dévotion,
Point de nouvelle opinion.
Vous mêlerez le tout ensemble,
En l'infusant, si bon vous semble,
Avec deux doigts du meilleur vin,
Que vous prendrez chaque matin.
Vous verrez que cette pratique,
Au médecin fera la nique [mockery].

One who Wishes to do Right.—The title "doctor" is not warranted. Surgeon and apothecary are the safe titles; others are questionable.

INCOME-TAX.

To the Editors of THE LANCET.

SIRS,—As in this district we have a new surveyor of taxes, who is very active in "putting on the screw," I advise my professional brethren to see that their life assurance premiums are properly deducted in the demand notes now being sent out before the tax is due.

I am, Sirs, yours obediently,

Dec. 29th, 1891. MARYLEBONE.

SPIRIT-WRITING IN THE FIFTEENTH CENTURY.

THE history of imposture and fraud, like the history of peoples and kingdoms, repeats itself, and there is nothing new under the sun. So that we are not surprised to find that the spirit-writing and precipitated letters were quite well known four centuries ago, as the following letter, taken from the Colloquies of Erasmus, which is worth quoting in part, shows:—

> "From the Imperial Heaven, Ides of September, Anno 1498. Under the Seal of my own ring.
>
> "Faunus, long a captive, but now free. To Faunus his gracious deliverer, sends eternal health. .... God has respected the pious intention of thy mind, and has delivered me from torments; and I now live happily among the angels. Thou hast a place appointed thee with St. Austin. .... In the meantime live merrily."

It is interesting to observe that it was transcribed, not on ordinary paper, but on a peculiar reddish paper, like that which "goldbeaters put their leaf in," and written in a strange antique character. There is no reason to believe that Erasmus fabricated the story of this imposture; the local colouring gives it an air of reality, and, as he says he was in company with men of judgment when the first part of the play was enacted, we can fancy his relating to Dean Colet and others of his learned friends this tale of the portentous apparition, the rumour of which in three days' time had spread over all England, and which was the prelude to the "precipitated" letter quoted above. We can also picture from his written account the merriment it created among that circle of wits, in no wise tender towards imposture or superstition, and especially delighted to have such a fling at the credulity of a priest. It is much to be desired that similar spirit communications and believers in them of the present day could be treated in the same wholesome manner.

D. W.—Unless otherwise stipulated by agreement, all fees are understood to be claimed by the principal. We state the rule, though it must be conceded that in some cases it bears hardly on assistants.

A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—I was much interested in Mr. Heath's suggestion of "digital pressure on the posterior half of the perineum as an aid to defecation." Let me suggest that the same effect can be produced by placing that portion of the perineum on the posterior edge of an oval commode, and, further, that the seat of an utensil can be made much more effectual for this purpose by having the slightest convex prominence at its posterior end. This can be added without the slightest discomfort to the patient. I am, Sirs, yours truly,

W. MURRAY, M.D., F.R.C.P.Lond.

Barrasford, Northumberland, Dec. 23rd, 1891.

IMPERFORATE ANUS.

Mr. W. G. Nash writes to draw our attention to the case which we published in the "Mirror of Hospital Practice," vol. i., 1891, p. 143, which bears a great similarity to the one which we inserted on p. 1335, vol. ii., and which had been under the care of Mr. Elliot.

Gwen Quinton might put her question to the editor of the *Nursing Record*, 11, Ludgate-hill, E.C.

A Subscriber.—Surely the "term now generally adopted" is "Death *under* Chloroform."

Mr. J. D. Lambert is thanked.

TREATMENT OF THREADWORM.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 19th, 1891, p. 1410, there is a reference to naphthalin as an anthelmintic, and it is there stated that it is very efficacious for the removal of threadworm. Will anyone who has used it for this purpose kindly give his experience as to its efficacy, mode of administration, and dose for young children? I have been treating two children (both under six years) with all the ordinary remedies for some time, but with little success. Any hints for treatment would be esteemed. I am, Sirs, yours faithfully,

Dec., 1891. X.

W. S. B.—We are not aware of its prevalence at Cheltenham or Malvern.

Mr. A. E. Edwards.—We cannot promise acceptance of the paper.

THE CLIMATE OF JAVA.

To the Editors of THE LANCET.

SIRS,—Could any of your readers give an intending visitor any information with regard to the climate of Java? The duration of the stay on the island would only be a few weeks. Would such a visit entail any exceptional risk to health, and which is the most favourable season for such a visit? I am, Sirs, yours faithfully,

Dec. 29th, 1891. VIATOR.

ABSTRACT OF THE

Lettsomian Lectures

ON THE

SURGICAL TREATMENT OF TRIGEMINAL NEURALGIA.

By WILLIAM ROSE, F.R.C.S.,

PROFESSOR OF SURGERY IN KING'S COLLEGE, AND SURGEON TO KING'S COLLEGE HOSPITAL.

LECTURE I.

AFTER a few introductory remarks as to the difficulty of selecting a subject which should touch on new ground, Mr. Rose considered that his recent experiences in the treatment of intractable facial tic might be interesting to the Fellows of the Society. The scanty details as to the morbid anatomy, and the unsatisfactory character of the statistical records, from the patients not having been kept under observation long enough, were noted, and a hope expressed that future investigations would be carried out more systematically. The temporary nature of the relief given by the usual operative means was alluded to, and the want of some more radical measure insisted on. He submitted that if the Gasserian ganglion could be removed without risk to life, it held out a better prospect of permanent relief than any other proceeding. Conrads' statistics were then quoted to show the frequency of this form of neuralgia.

Before dealing with the surgical treatment of this disease the lecturer thought it would not be out of place to allude briefly to the causes which produce this condition, and to the symptoms associated therewith, inasmuch as an accurate estimate of these must be formed as a basis of scientific treatment. The following was suggested as a convenient etiological classification:—1. Intracranial causes—cerebral, radical, ganglionic. 2. Cranial. 3. Extracranial or peripheral. 4. Toxic—e.g., mercury, lead, or malaria. 5. Reflex. 6. Functional.

Under *cerebral* causes were mentioned sclerosis, aneurysms, and tumours interfering with the deep origins of the nerve in the pons and medulla. Dr. Putnam's able paper[1] was referred to, from which the following predisposing factors of central disease were quoted:—(1) The large extent of the deep origins, and hence the existence of wide connexions with other nerve tracks rendering this nerve more liable to be affected at its origin by morbid influences from many extraneous sources independent of its own area of distribution, and (2) the elaborate and delicate organisation of the centres, as evidenced by the exquisite sensibility of the parts connected with it—e.g., the lips, tongue, and eyes. Dr. Putnam also maintained that inflammatory changes may occur in a nerve as a result of frequent and severe nerve-storms passing along it.

Radical causes.—Any inflammatory affection of the dural sheath lining the fibrous canal through which the root of the nerve passes on its way from the pons to the ganglion was suggested as a possible origin of the disease.

Ganglionic causes.—Chronic interstitial inflammatory changes pressing on the nerve cells were present in one of the author's cases, and such may probably be a starting point of the neuralgic condition. Carnochan's opinion as to the function of Meckel's ganglion was mentioned.

Under *cranial* causes were included all the morbid processes occurring at the base of the skull and the foramina in it through which the nerves pass. Bony and malignant tumours, callus from fractures, and syphilitic periostitis were alluded to, and some observations made by Mr. Carless on the shape and size of the foramen ovale were introduced to illustrate the fact that the foramina are smaller in females than in males; that the foramina are inconstant in lumen and often asymmetrical, and that in form they may vary from nearly a circle, seven or eight millimetres in diameter, to a narrow slit not more than two millimetres broad. They were stated not to vary at all regularly with the age of the patient, but more with the shape and size of the cranium.

The *peripheral* causes were next dealt with, and special attention was devoted to three conditions: 1. Dental caries was a fruitful source of the trouble, and it was alleged that neuralgia might be started by a tooth which is itself not painful and might be increased by its extraction. The filling-up of the alveoli of edentulous jaws with bone, which compresses the nerve filaments, as described by Gross, was stated to have been relieved by the removal of wedge-shaped pieces of bone or by drilling into them. 2. The condition of the peripheral bony canals had long been recognised as a potent factor in the production of the disease, especially in cases where the infra-orbital and inferior dental nerves are affected. The non-occurrence of neuralgia in children when these canals are widest was mentioned, also the fact that a contraction of their lumen had been met with on the operating table. Unfortunately, though the cause might be removed the effect remained, and often tended to spread upward. 3. Exposure to cold or damp was also noted as being associated closely with the production of the disease, and presumably the pathological condition present was a rheumatic perineuritis producing pressure upon the nervi nervorum. Retention of secretion in the frontal sinuses (Horner and Seelig-Müller), disease of the ear (Tröltsch and Moos), implication of the nerves in cicatrices, impaction of foreign bodies, &c., were also included in this division.

The *toxic*, *reflex*, and *functional* causes were summarily dismissed, but importance was attached to a morbid neurotic temperament, either inherited or acquired; to anæmia, and to worry as predisposing, if not exciting, causes of the pain.

A marked distinction was drawn between the simple forms of the disease and the severe variety known as tic-douloureux or epileptiform neuralgia. The latter term is a modification of the name suggested by Trousseau—viz., "tic epileptiforme," and the similarity of the paroxysmal attack to an epileptic seizure was commented on. This severe variety is more common in the second and third divisions of the nerve than in the first, the infra-orbital and inferior dental branches being especially liable to it. The simple form would appear to more commonly affect the ophthalmic division, and it is now generally acknowledged that supra-orbital neuralgia is more closely associated with central neurosal conditions, such as migraine, &c., rather than with tic. The amenability of this form to quinine, and the frequent periodicity of the attacks, have suggested the term "brow-ague," so often applied to it, although there is no absolute evidence connecting it with malarial poisoning.

The pathological anatomy was next dealt with, and Professor Dana's recent paper in the *American Journal of Nervous and Mental Disease* (No. 1, 1891) commented on. This author maintains that although many causes of inveterate facial tic are due to definite local lesions—such as tumours, aneurysms, &c.,—yet the majority are due not even to a neuritis of the branches affected, but rather to an obliterative endarteritis of the vessels supplying the nerve.

The microscopical appearances of the excised nerves were alluded to, the observations of Mr. Horsley,[2] Dr. Putnam,[3] and Prof. Schweinitz[4] collaborated. The axis cylinders are found swollen or shrunken, and sometimes have disappeared entirely; they are usually difficult to stain with either logwood or carmine. The medullary substance often appears swollen, and the sections of the tubules are not clear and sharply defined, but consist of a confused mass of concentric rings. "The transverse section of nerve fibres might in places be not incorrectly compared to the interior aspect of a minute oyster-shell both in shape and by virtue of this peculiar concentric arrangement" (Schweinitz). The sheath of Schwann is crumpled up more or less, and its nuclei increased in numbers. The interstitial connective tissue (or endoneurium) is also increased in amount, especially around the bloodvessels. These appearances are similar to those seen in a case of chronic neuritis, and that of an ascending character, the changes being often more marked peripherally than at the central end. Putnam notes the fact that all the fibres in a nerve are not invariably affected in the same way, and often healthy and diseased tubules may be seen in the same section lying side by side. The perineurium is also in some cases thickened, and some observers have noticed small nerve bundles lying in this tissue with the fibres very much changed. These are probably the remains of the "nervi nervorum" described by the late Mr. John Marshall,

the compression of which may possibly be one of the chief factors in the production of the pain.

Turning to the clinical aspect of the disease, the leading symptoms of a typical case were given as follows: The patient, usually a female, and probably in the middle period of life, complains of more or less periodic attacks of severe unilateral cumulative pain, darting along special nerve tracks, and referred particularly to the points of exit of the peripheral branches upon the face, especally to those of the second and third divisions. The attacks, after reaching a certain pitch of severity, suddenly subside, leaving the patient intervals of freedom, which, as the complaint advances, become proportionately diminished. As these intervals become shortened, so does the general tone of the nervous system become sympathetically lowered from anxious apprehension and dread of the return of the pain. As a severe paroxysm of pain frequently follows any touching of the affected parts of the face, patients guard them most jealously; washing even is avoided; and the lecturer had seen many such cases where the side of the face was distinctly dirty from this cause. Similarly the tongue may become thickly covered with fur on the affected side in consequence mainly of the patient using only the opposite side of the mouth in mastication, but possibly also to trophic disturbance. Stimuli reaching the centres from other sources, such as the mere slamming of a door, any sudden noise, or a draught of air, will suffice in like manner to precipitate an attack, so that the patients live in a morbid state of dread. In the midst of speaking, laughing, coughing, and particularly chewing, a paroxysm may occur with lightning-like rapidity, causing a sudden cessation of any of these acts. The special character of the pain must be carefully noted as being entirely different from those migratory or wandering pains which often attack these patients in the intervals between the paroxysms of true tic, and which might mislead the medical attendant in arriving at a decision as to the exact seat of the lesion. Those who have long suffered from this disease look upon them as trifling in comparison with the agony of which they are so frequently the precursors. Abnormal conditions of the motor, vaso-motor, and secretory apparatus also form part of a typically severe attack. Spasmodic or paralytic motor symptoms may be seen, more commonly the former; in neuralgia of the third division, for example, the muscles of the jaw, face, and even those rotating the head, may be spasmodically contracted. There is often an abundant flow of mucus from the nose, as well as of saliva and tears accompanying the attack, whilst beads of perspiration often stand upon the affected side of the forehead and face. Again, vaso-motor paralysis is manifested in a reddening and heightened temperature of the side of the face, with swelling of the veins, and the conjunctiva may be similarly affected. As a result of this, in old long-standing cases, the lips may become thickened and tumefied from chronic inflammatory hyperplasia.

The *differential diagnosis* was discussed and the importance emphasised of ascertaining, if possible, the exact site of the lesion. The previous history and surroundings of the patient should be carefully investigated, special stress being laid on possible injuries to the soft and hard structures in any part of the area of distribution of the nerve. The teeth should be examined by a skilled dentist, and old stumps removed. In women the condition of the uterus and ovaries, and the regularity or not of the menstrual functions, should also be noted. But even if the case be due to some central lesion, the lecturer maintained that operative measures may be distinctly of value in relieving the pain, and he discussed Bell's and Wagner's theories to explain this occurrence.

After a passing allusion to the medical treatment, general and local, and to the use of hypnotism, the different means of dealing directly with the nerves surgically were described as follows:—

In reviewing generally the *operative treatment* of this disease, the first and simplest method employed, that of *neurotomy*, was suggested by Albinus and Galen, and first carried out on a branch of the fifth nerve by Schlichting and Maréchal about 150 years ago, but good results did not follow their efforts. It was performed more or less frequently up to 1840, and then for a decade or more seems to have fallen into disuse, if the silence of records is to be so interpreted. But in 1852, M. Roux of Paris recorded four cases of operation on the fifth nerve, since which time they have become numerous enough. The plan usually adopted was that of introducing subcutaneously or under the mucous membrane a fine tenotome and so dividing the nerve, whilst in a few cases the open method was employed. Transient relief followed in some instances, but not in all; and usually the neuralgic pain recurred at an early date with all its old severity. The cause of this is not far to seek, in that we now know how very readily divided nerves reunite, and even when a portion of a nerve trunk is entirely removed, regeneration of the destroyed portion is a matter of frequent experience. The scar itself, moreover, may become the exciting cause of the relapse and may require extirpation. To prevent this reunion of the nerve, *neurectomy* on a more extensive scale naturally suggested itself, and in this country it was performed for the first time by Abernethy in 1793. Even then insufficient portions of the nerve trunks were removed, seldom more than half an inch, so that the regenerative energy of the nerve soon bridged over the interval, and the pain recurred. Many other plans were suggested to obviate this. Thus, in 1822 Klein crushed and cauterised the central end; Middledorpff, Bardeleben, and Luikart divided the nerve with the galvano-cautery; Boyer cauterised the peripheral end; whilst Malgaigne split one or both ends longitudinally and turned them back in a loop manner, in other cases attempting to place a flap of soft tissue between the two ends. M. Péan more recently has recommended the old plan of removing the central end by cauterisation. The results of all these earlier operations, whether neurotomy or neurectomy, were not satisfactory, as the following statistics will show:—Otto Weber[5] collected 100 cases with only 18 cures. Wagner in 1869 recorded 135 cases (possibly including Weber's) and the results given were:—Cures after three years, 18; fatalities from sepsis, 6; in 1 case only, relief was experienced for less than a month; in 32 cases, it continued for months; in 20 cases from one to three years; in 24 the relief was temporary, but the after-history was not known. Dr. Fowler of Brooklyn[6] collected 83 cases recorded since Wagner's list was published; but the statistics are of comparatively little value, as so many of the patients were kept under observation for but a short time.

The regenerative energy of the nerve was shown not to be the only cause of the relapses. Attention was directed to the important fact that so many of the branches of the nerve passed through bony canals, and were thus more directly exposed to pressure, whilst it was also noted that during the period of life when these bony canals were relatively widest—i.e., among children—neuralgia is practically unknown. The suggestion naturally followed that the nerves should always be divided on the proximal side of the canals.

As to the extent of the operation of neurectomy, it is eminently desirable to divide the nerve as high as possible, in order to get above any undiscovered lesion; whilst it is also advisable to remove as much of the nerve peripherally as is practicable in the affected locality, in order to give the nerve centre as much rest as possible, and prevent stimuli from reaching the brain along anastomosing trunks. Mr. Rose continued: "The removal of a large extent of the nerve trunk was first suggested, I believe, by Professor Braun as a means of dealing with the infra-orbital nerve; he advised its division at the foramen rotundum, and also at the infra-orbital foramen, removing the whole of the intervening portion by traction. M. Beau of Toulon recommended a similar process to be adopted in the treatment of the inferior dental branch, dividing it at its entrance to the dental canal, and at its exit from the mental foramen, and removing the part between. But it was Professor Thiersch,[7] who carried out this plan of *nerve-extraction* more thoroughly, and extended the operation to all the divisions of the trigeminal. He frees the nerve from its connexions at some spot easily accessible, and then by a process of torsion with specially constructed forceps he is able to draw out a considerable length of it both distally and proximally, tearing the central end away and cutting the peripheral. By this means very large portions of the nerve can be removed, and so, it is hoped, recurrence of the neuralgia more effectually prevented. He recorded twenty-eight cases of the operation in 1889, performed on seventeen different patients, having operated eleven times on the infra-orbital,

five times on the supra-orbital, four times on the inferior dental, thrice on the lingual, and once on the mental. Five or six centimetres can be removed from the supra-orbital; and he showed two specimens of the lingual nerve that had been extracted from the cadaver, 9·5 and 15 centimetres in length respectively. Of the second specimen 6 centimetres were central, and 9 peripheral, measured from the angle of the jaw beneath which the nerve was grasped; and he calculated that it was torn through only one or two centimetres from the Gasserian ganglion. As to his results on the living subject, a marked degree of success attended his practice. Only one case had relapsed, and that in a very hysterical subject; several of the operations had been performed six years previously. Paresis of the facial muscles had occurred temporarily in a few instances, and this is attributed to damage to the facial nerve terminals through the avulsion of the sensory twigs distributed with them.

"The value of *nerve stretching* as a means of treatment was accidentally discovered by Nussbaum of Munich in 1860, from the disappearance of a tetanic spasm of the arm after an accidental stretching of the ulnar nerve during resection of the elbow. In 1861 Hauser similarly by chance cured a contraction of the fourth and fifth fingers; and in 1869 Billroth[8] unintentionally cured a case of sciatica by the traction made during a thorough examination of the sciatic nerve. But it was Nussbaum who reduced this plan of treatment to method, and first deliberately stretched the brachial plexus in 1874,[9] whilst Vogt in 1876 appears to have been the first to use it in trigeminal neuralgia. Since that date the operation has been largely employed, and its value has been pretty accurately ascertained in the treatment of the many conditions to which it has been applied. Its use in cases of neuralgia has not been very satisfactory, and especially is this so in facial tic. Statistics are not of much value in the investigation of this subject, inasmuch as the cases were kept under observation for so short a time. Hahn of Berlin records eleven cases, however, of which eight relapsed after six or eight months, two were utter failures, and only one case was really improved, although not cured, and in this a portion of the nerve was excised after being stretched. Lagrange gives somewhat similar unsatisfactory accounts of the operation of stretching the supra-orbital nerve; out of fifteen cases there was but one known cure after three years, and five were quite unsuccessful; in one there was but temporary relief, and the subsequent histories of the other cases is not recorded. Of six neurectomies of the same nerve, four were successful. The same author contrasts neurectomy with nerve stretching of the infra-orbital nerve; and whilst with the former 25·67 per cent. of the cases remained free from pain after three years, only 12·57 per cent. of those in which the nerve was stretched were similarly free at the same time. Practically it is now admitted by almost all surgeons that nerve stretching should be retained as a means of dealing with neuralgia of mixed nerves only, and undoubtedly it is beneficial in some such cases. But with the fifth nerve, which is almost entirely sensory, no permanent relief can be expected from the operation, and neurectomy is infinitely to be preferred. Probably, however, in all cases of neurectomy, a certain amount of stretching of both central and peripheral ends accompanies the manipulations necessary to free the trunks, and it is a perfectly open question as to whether or not such traction has any beneficial effect or otherwise on the course of the disease. That central changes can result is now a fact tolerably well established in those instances where the nerves pass directly through short, straight canals to the central organ. Thus Dr. Pauline Tarnowski, in the *Archives de Neurologie* (May and July, 1885), has reported the results of experiments made by him on rabbits. The sciatic nerves were stretched, and the spinal cords carefully examined at varying intervals of time. If slight traction alone was employed—e.g., 500 grammes—the only change found was a transient hyperæmia which soon passed away. But when the force reached four or five kilogrammes more definite changes occurred, unnecessary to particularise here, beyond stating that in the grey matter hæmorrhages and inflammatory exudations were seen soon after the injury, and later on sclerosis with atrophy of the nerve cells, such changes being always more marked in the posterior than in the anterior cornua. It is quite probable that similar effects may be produced in the Gasserian ganglion by stretching the branches of the third division, but evidently sufficient curative effect is not thereby established.

"One other plan of treatment which has been suggested must be alluded to—viz., *ligature of the carotid artery*. It was originally recommended and practised by Trousseau, and up to the present time, so far as I can ascertain, but eighteen cases have been thus treated, and the results as given by Dr. Fowler have been as follows:—In four cases there was relief for over three years, in three for fifteen months, in four for one year, in one case there was only partial relief, and in two cases no relief. One case was fatal. The longest period of relief was eleven years, but it must be noted that some of the reported cures had also been treated by nerve stretching and excision. Roser is stated by Madelung[10] to have tied the external carotid for tic thrice, with one cure. Of this plan I have had no experience, and, indeed, have heard of no cases in which it has been recently tried; but one cannot help being struck by the above results, especially in connexion with the theory of obliterative endarteritis, alluded to earlier in this lecture propounded by Professor Dana. The figures quoted indicate a measure of success which is certainly somewhat greater than that usually attending operations directed to the nerves themselves. The mortality of the operation is a serious objection to it, for whilst it will be less than when the artery is tied for aneurysms &c, Hüter calculates it is about 5 per cent. in these cases, and such a fact would exclude it as a means of treatment, except as a last resort. Moreover, even if not fatal, the possible effect upon the cerebral hemispheres must not be lost sight of in advising such a plan of treatment. That death has occurred from neurectomy is an undoubted fact, but this is usually explained by septic contamination of the wound which can be avoided, and I am thankful to state that I have not yet lost a case in any of my nerve operations. Should, however, a recurrence of the pain occur after dealing with the Gasserian ganglion, this operation of carotid ligature can still be resorted to."

Clinical Lectures
ON
STRICTURE OF THE ŒSOPHAGUS,
WITH FOURTEEN ILLUSTRATIVE CASES, IN FOUR OF WHICH GASTROSTOMY WAS SUCCESSFULLY PERFORMED.

BY DAVID NEWMAN, M.D.,
SURGEON TO THE DEPARTMENT FOR DISEASES OF THE THROAT AND NOSE AT THE ROYAL INFIRMARY, AND ASSISTANT SURGEON TO THE WESTERN INFIRMARY, GLASGOW.

LECTURE I. (*Concluded.*)

IN the second class of cases—viz., those where the growth has developed at the level of the bifurcation of the trachea, the supervention of dysphagia is generally, other conditions being equal, more gradual, but the special points in diagnosis are more difficult and various.

During the session we have had two cases of cancer at the level of the bifurcation of the trachea, and in both the development of difficulty in swallowing has been very gradual.

CASE 5. *Epithelioma of the œsophagus at the level of the bifurcation of the trachea; ulceration and rupture into the aorta; early symptoms, dysphagia, afterwards improving, dyspnœa, unequal inspiration in lungs; dull area posteriorly; death from hæmorrhage*.—G. A——, aged fifty-seven, was admitted into the Glasgow Royal Infirmary on March 25th, 1890, complaining of difficulty in swallowing, which, he said, commenced at the beginning of December, 1889. The first difficulty he experienced was in swallowing solid food, and this gradually increased until the middle of February in the present year, when he had to give up taking solids, and since that time his diet has been composed entirely of liquid food. During the act of swallowing he feels as if the difficulty in deglutition was caused by con-

Digitized by Google

striction at the level of the cricoid cartilage, but once the bolus has passed that point it occasions him no trouble, nor has he ever suffered from vomiting, cough, alteration in the voice, or pain. The pupils are equal, and the radial pulses are synchronous and equal in force, although somewhat weaker than normal. On passing a bougie (No. 16) a complete obstruction is met with, thirteen inches from the teeth, so that the stricture of the œsophagus may be said to be situated between the level of the supra-sternal notch and that of the bifurcation of the trachea. The largest size of bougie which passed through the stricture was a No. 6. On inquiring into the history of the case, no evidence could be found to show that the patient at any time suffered from syphilis, or sustained any traumatic injury to the œsophagus. On palpating the neck, nothing abnormal could be discovered in the line of the gullet or in the lymphatic glands. The larynx and trachea, as far as could be seen, were quite healthy, but on the least exertion the patient suffered from well-marked dyspnœa.

Physical examination of the chest showed the cardiac sounds to be pure, but feeble, and very irregular in rhythm; but there was no evidence of valvular disease. I did not examine the condition of the lungs critically, but posteriorly, in the interscapular space and to the left side of the spine, on a level with the fourth dorsal vertebra, and extending upwards and downwards from that point, there could be detected a distinct localised dulness occupying an area of about three or four square inches. Associated with this dulness on the left side, and about the same level as the obstruction in the œsophagus, there was evidence that air was not entering the left lung as freely as the right.

The patient was sent to Dr. Jas. Wallace Anderson, who kindly furnished me with the following report: "The upper left front of the thorax is slightly retracted, and there is a corresponding diminution of expansion; there also being a rather increased resonance on percussion over the same area The respiratory murmur over this area is less full and free than on the right side, at some points being hardly audible, at others of a whiffling, wavy character, but always faint. Posteriorly there is a mere suspicion of dulness in the upper left interscapular region. The respiratory murmur is distinctly fainter on the left side at the level of the third, fourth, and fifth dorsal vertebræ, and this diminution is continued one or two vertebræ lower on that side. The respiratory murmur over the left lung generally, though quite audible, is fainter than on the right side. There is no alteration in the vocal resonance, and no râles are heard anywhere. Cardiac phenomena and circulation generally are all perfectly natural."

At this time (April 1st) I was quite satisfied that the case was one of cancer of the œsophagus, but as there was no demand for surgical interference I transferred the patient to Dr. Wallace Anderson's care. During his residence in Dr. Anderson's ward he was kept at rest in bed, and as a result of treatment the symptoms became less pronounced, and the patient desired to be dismissed, and to return to his ordinary employment. Between April 1st and May 24th great improvement took place in his power of swallowing, and he gained in weight; so that when he was dismissed he was able to swallow not only fluids with freedom, but with a little care solid food as well. This improvement, with freedom from pain in swallowing, and the absence of vomiting, emaciation, or anæmia, led me to doubt the accuracy of my first diagnosis, and consider whether or not the dysphagia and impaired respiration on the left side might not be due to the presence of an aneurysm or solid tumour at the bifurcation of the trachea. A large-sized bougie now passed with ease. During the summer months the patient enjoyed moderately good health, and was able to swallow well both fluid and semi-fluid food; but in the autumn he again began to suffer from dysphagia, and he stated that since he was dismissed from the infirmary he suffered greatly from breathlessness. Patient was re-admitted into my ward on Oct. 7th. On passing a bougie (No. 12) it was found to be impossible to get it past thirteen inches from the teeth. At this time I went over the case very carefully again, and found the patient to be very much in the same condition as in April, except that, perhaps, he suffered more from dyspnœa, and I made a note in the journal to the effect that "although there are no positive signs of aneurysm, the situation of the obstruction, the dyspnœa, the impaired respiration on the left side, the area of dulness posteriorly, and the history of the case, raise the gravest suspicion of an aneurysm at the bifurcation of the trachea." On Oct. 18th the patient spat up a small quantity of dark blood, and for the first time complained of pain in the chest. On the 28th he again suffered from a deep-seated gnawing pain in the præcordial region, and when I saw him in the morning he was looking very ill. At 1 o'clock on the following morning the patient raised himself in bed suddenly, because of some distress referred to the chest. Immediately he sank back on the pillow and became blanched, his pulse at that time being small and thready, and a few minutes afterwards almost imperceptible, while he continued to breathe after the pulse had ceased.[1] The breathing was of a sighing nature. Between each respiration an interval of about half a minute occurred, which gradually increased until the breathing ceased altogether. This form of respiration lasted for about eight minutes.

Post-mortem examination revealed a malignant perforating ulcer of the œsophagus opening into the thoracic aorta, causing fatal hæmorrhage into the stomach and intestine. Dr. Lindsay Steven's report was as follows:—"The pericardium contains about three ounces of slightly blood-stained serum. The heart is very soft and flabby, and its external fat is much increased on the surface of the right ventricle. The aortic and pulmonary curtains are competent. There is slight atheroma a little above the free margins of the semilunar curtains, but the orifices of the coronary arteries are patent. The muscular tissue is very soft, but on the whole normal looking. On cutting into the septum, slight yellowishness of the fibres is observed. The lungs, trachea, and gullet are removed together. The left lung is pretty generally and moderately firmly adherent, the pleura in this situation being of cartilaginous hardness, and perhaps even slightly calcareous in parts. This very firm adhesion on the left side extends upwards as far as the fifth or sixth dorsal vertebra, but does not extend round towards the front. After the thoracic viscera have been removed, a probe is passed into the gullet from above, and its further progress downwards is completely arrested at the level of the bifurcation of the trachea. On passing the probe from the gastric end of the gullet, it passes through the entire length of the tube without any difficulty. The trachea is then opened along its posterior wall, almost to the bifurcation, but nothing abnormal is seen in it. The thoracic aorta is then laid open by cutting with the scissors from below upwards. Its internal coat presents tolerably healthy characters, but about an inch below the arch, and towards its posterior border, a circular opening with thin and somewhat ragged edges is found; this opening leads into a ragged cavity. The gullet is next laid open, and at the level of the obstruction just mentioned a large ragged ulcerated cavity containing débris of blood-clot and broken-down tissue is found in its wall. The upper margin of this excavation is raised and rather sharp, and presents the typical characters of the margin of a malignant ulcer. The cavity had evidently eaten its way into the aorta, and produced the aperture in that vessel described above. It should also be noted that the wall of the aorta, in the neighbourhood of the aperture, which is about the size of a threepenny-piece, is somewhat thinned." The other case is still in the ward.

CASE 6. *Scirrhus of the œsophagus at the level of the bifurcation of the trachea; very slow development of symptoms; gastrostomy successful.*—J. P——, aged fifty-six, admitted into the infirmary on Jan. 26th, 1891. On inquiring into the history of the case it appears that about six months ago he experienced slight difficulty in swallowing such articles of diet as butcher's meat, potatoes, and fish, but after a few attempts he was able to take a satisfactory meal. From being slight, the dysphagia steadily became more marked, so that within two months of the onset of the symptoms he found that after taking a few mouthfuls of food just mentioned his gullet got filled up, and he felt a choking sensation in his throat. Sometimes after repeated attempts at swallowing such food was ejected, but he found little difficulty in swallowing oatmeal cake, porridge, or snow-cake. Soft bread was swallowed with greater difficulty. Fluid food has always been swallowed with ease. Between June and December, 1890, the patient's weight was reduced 28 lb. When admitted into the hospital he was unable to swallow solid food, and had not eaten butcher's meat for some weeks. He was able, however, to take porridge, very finely minced meat, and bread

[1] The mode of death was observed and described by Dr. J. G. Gray, the resident assistant, who kept careful notes of the case.

Digitized by Google

when partaken of along with a good quantity of fluid. On passing an œsophageal bougie a firm stricture is discovered thirteen inches and a half from the teeth. From the situation of the stricture the question was at once raised whether the obstruction to swallowing was due to pressure from without, or to the presence of a growth within, the gullet. Careful physical examination of the chest made by Dr. Wallace Anderson and myself showed the thoracic organs to be quite normal. On auscultation of the œsophagus the act of deglutition was shown to be delayed and prolonged below the level of the third dorsal vertebra. There was no evidence of pouching of the œsophagus above the seat of obstruction, and on all occasions the quantity of food which regurgitated was never greater than what was last swallowed. At no time has the patient suffered pain, nor has blood been observed in the vomited matter. No history of injury or of syphilitic disease. During the time the patient was in the ward his general condition improved, and his weight was maintained at from 138 lb. to 139 lb. After being in the ward for two months he was dismissed, and requested to report himself once a fortnight. The patient returned to the Royal Infirmary, and gastrostomy was successfully performed in December, 1891. The patient was still able to swallow some food by the mouth.

When an obstruction to swallowing is detected at the level of the bifurcation of the trachea great care must be taken in the passage of bougies. While I was pathologist to the Royal Infirmary a case came under my observation where a very complete obstruction to swallowing was caused by an aneurysm of the aorta. In this case a physician, supposing the obstruction to be due to a tumour in the gullet, passed a bougie, and perforated, not only the œsophagus, but the wall of the aorta. The hæmorrhage which resulted caused the patient to be sent to the Royal Infirmary, and she died shortly after admission. This case made a very strong impression upon my mind, and, as a consequence, I have been most careful, when I discover an obstruction in the situation indicated, to avoid the passage of bougies unless it is very evident that there is no aneurysm or ulceration of the œsophagus.

In other cases difficulty in diagnosis is only experienced during the early stage of the case, when, with evidence of well-marked obstruction in the œsophagus, there are no physical signs directly pointing to aneurysm, and the only symptom which leads one to suspect serious disease of the aorta is paralysis of the left vocal cord. The value of this symptom in distinguishing between aneurysm and other causes of œsophageal obstruction is considerable, and in one of the cases seen this session it, to a great extent, prejudiced my mind in favour of aortic aneurysm as the cause of the dysphagia, even although no other symptoms pointed in the same way. And while it is quite true that, in a few exceptional cases, unilateral paralysis of the muscles supplied by the inferior laryngeal nerve may be caused by other conditions, I think it is of the utmost importance to bear in mind the undoubted fact that aneurysm of the transverse arch causes paralysis in the large majority of cases. Indeed, for practical purposes, it may be looked upon as the cause of paralysis in nineteen out of twenty cases. Undoubtedly cases have been recorded in which paralysis of the left recurrent laryngeal nerve has been the result of pressure by tumours in the œsophagus,[2] by enlarged bronchial glands, by pleuritic adhesions or fibroid induration of the apex of the left lung, by enlargement of the thyroid body, by great pericardial exudation, or by hypertrophy of the heart, leading by pressure or displacement to interference with the function of the nerve. The answer to the question, What is the cause of the paralysis? is usually easy, but in a few cases it is almost impossible to give a definite reply. In such cases, I would say, treat the case as one of aneurysm of the aorta. In my experience I have seen a considerable number of these at first obscure cases, and in the large majority they have proved in the end the accuracy of the statement I have just made.

The remaining class of cases—namely, those where the cancerous formation is situated at the lower end of the œsophagus has also been well illustrated in the three following cases.

CASE 7. *Epithelioma of lower end of œsophagus; history of sudden and steadily increasing dysphagia, culminating in almost complete obstruction; gastrostomy in two stages, followed by improvement in swallowing.*—W. H——, a labourer aged sixty-eight, was admitted into the Glasgow Royal Infirmary on Oct. 7th, 1890. He stated that about five weeks previous to admission he found one day that he was unable to swallow any solid food, although still able to swallow fluid and semi-fluid diet, some articles of food passing into the stomach more easily than others. As a rule, he experienced greater difficulty in swallowing hot than cold substances. Since the onset of these symptoms the dysphagia has steadily become worse, so that on admission the patient was greatly emaciated, his weight being reduced from 16 st. to 9 st. 10 lb. Now if fluid food be swallowed rapidly or in any quantity at a time, it is ejected with considerable force. There is no evidence of any pouching of the œsophagus above the seat of obstruction, the quantity of food vomited being only what has been last swallowed. On passing a full-sized bougie an obstruction is met with at the lower end of the œsophagus, which, on further examination, is found to permit the passage of a No. 10 œsophageal bougie. The patient stated that he had not suffered pain at any time, nor had he noticed any blood in the vomited matter. There was no history of injury or of syphilis. In respect to treatment little has to be said, the principal object being to introduce as much nourishment as possible in a concentrated form both by stomach and by nutrient, zyminised suppositories, and enemata.—Oct. 27th: Since admission the dysphagia has become steadily worse, so that now the patient is unable to swallow more than a few spoonfuls of fluid in the twenty-four hours. His weight is now 9 st. 1 lb. Gastrostomy was therefore performed, and the patient made a good recovery.[3]

CASE 8. *Epithelioma of the lower end of the œsophagus.*—J. F——, aged sixty-three, was shown to you at a demonstration last week. It appears that he first experienced a difficulty in taking solid food on Oct. 16th, 1890, and since that date the dysphagia has steadily increased, so that at present he is only able to take cold fluid food. During this period his weight diminished from 160 lb. to 130 lb., and he is now very anæmic and complains much of weakness. He had no morbid sensation in the throat, further than what is produced by a regurgitation of food, and sometimes the quantity which accumulates above the stricture amounts to more than one pint. When he attempts to swallow food rapidly, or in considerable quantity at a time, it is suddenly ejected with force, and not infrequently flows into the nostrils and larynx. He has never noticed any blood in the vomited matter. On introducing a full-sized bougie a stricture is detected at the lower end of the œsophagus, through which not even the smallest size of bougie can be passed. A careful physical examination of the chest fails to reveal any abnormality of the thoracic organs, further than that the action of the heart is feeble and the pulse numbers from 55 to 65 per minute. The patient was very anæmic and extremely weak from want of food, and he was advised to come into the hospital immediately, but this he failed to do. Since I examined him before you he has not been seen by me. He left the hospital, and probably we will see him no more.

CASE 9. *Acute carcinoma at the lower end of the œsophagus involving cardiac end of stomach; death from collapse.*—H. C——, aged seventy-one, was admitted into the hospital on Jan. 30th, 1891. Four months previous to admission the patient enjoyed perfect health, and was able to take his food without the slightest difficulty, but he noticed that his appetite was not so good as formerly, and this want of desire for food continued until the beginning of December, when he noticed for the first time difficulty in swallowing certain kinds of food, such as potatoes, bread, and butcher's meat. At the beginning of the month, the difficulty in deglutition was but slight; the dysphagia, however, steadily and rapidly increased, so that by the beginning of the year 1891 he was quite unable to swallow any solid food, and during the first fortnight of January he had taken nothing but a little sherry negus, and a few spoonfuls of beef-tea occasionally. His ordinary weight was 174 lb., but on admission he weighed only 141½ lb., and considering that his height is 5 ft. 11½ in. he looks very much emaciated. The pulse was firm and strong, and numbered 100 beats per minute. Little or no anæmia and no pain. On passing an œsophageal bougie a complete obstruction is met with close to the stomach. The stricture is so complete that it is with the greatest difficulty a No. 3 bougie was passed. As a consequence of the extremely weak condition of the patient, and

[2] In Case 4, before the patient left the ward there was complete paralysis of the left vocal cord.

[3] Patient progressed favourably during the early summer, and the disease advanced very slowly; but, not receiving proper attention at home, he was found dead in bed from starvation in August.

Digitized by Google

his inability to take food by the mouth, he was fed by the rectum by means of beef peptonoids, peptonised beef-tea, and meat suppositories. Physical examination of the chest gave the following results:—The sounds of the heart are feeble, but there is no evidence of organic disease. Lungs normal. On palpating the abdomen the liver is found to project downwards beyond the costal cartilages for a distance of about one inch and a half, but on percussion the hepatic dulness is not found to be increased, and no nodules can be discovered. To the left of the liver the percussion is equivocal, and to the hand there is a marked resistance in the region of the stomach. Other abdominal organs normal. From the circumstance that the obstruction was situated so low down and was associated with marked resistance in the region of the stomach, which indicated that that organ was involved in the disease, I resolved not to operate, and the patient died in a few days from collapse.

The necropsy showed the thoracic organs to be normal. The liver was found to be displaced downwards and to the left, so that the left lobe overlapped and hid from view the contracted and empty stomach. At the lower end of the œsophagus, and along the neighbouring parts of the stomach, there was a large and widespread malignant ulcer, and the substance of the tumour involved the entire thickness of the stomach wall throughout an area of about four inches square, the greater part of which occupied the greater curvature. The tumour was an encephaloid carcinoma. There were no secondary formations.

With these cases before you it is at once obvious that not only the symptoms during life, but also the mode of death, are determined by the situation as well as by the precise nature of the malignant disease. It is clear I think that even a slow-growing epithelioma, if situated in the uppermost part of the œsophagus (as, for example, in Cases 3 and 4), will lead to death by starvation sooner than a more rapidly growing tumour situated at the level of the bifurcation of the trachea, or at the lower end of the œsophagus—e.g., Cases 5, 6, 7, and 8. Putting the question of situation of the tumour out of account for the moment, and, other conditions being equal, I think it may be safely said that adenoid cancer grows most rapidly, and, if not interfered with, causes death in the shortest time. Epithelioma is less acute, while scirrhous cancer, as shown in Cases 2 and 6, may remain practically stationary for a considerable period. As will be observed by reference to the cases I have demonstrated to you, the most prominent and constant symptom is dysphagia, which, as a rule, is at first slight in degree, but gradually and steadily progressive, at first occasional, but afterwards always present. In some cases, on the other hand, the difficulty in swallowing develops suddenly, and is from the beginning severe. This is experienced when the tumour is situated high up, but if the lower part of the gullet be attacked in not a few instances the patient only complains of severe difficulty in deglutition after the disease has been shown to exist for some considerable time. The usual experience is that solids, especially bread, potatoes, and butcher's meat, when taken in quantity, fail to pass a certain point in the gullet where the bolus may become lodged, or it may be found necessary to wash down each morsel by a draught of fluid, and even this may only succeed after careful mastication and repeated unsuccessful attempts. The patient may imagine that he has managed to swallow a moderately good meal, when, to his disgust, in a short time the greater part of it wells back into his mouth. This temporary retention of the food is possible only when the œsophagus has become pouched above the stricture. At first the quantity of food so retained is small in amount, and regurgitates almost immediately after it is swallowed; but as time advances the sac may become of considerable size, and capable of retaining large quantities of food. The regurgitation observed in such cases is very different from what is noticed in cases of spasmodic stricture or in ordinary vomiting of the stomach, in so far that the contents of the pouch simply well up, and resembles the vomiting resulting from cerebral disease more closely than any other form of sickness. When ulceration occurs sometimes the dysphagia is relieved to some extent, but at the same time the vomited matter is no longer simply the food as it was swallowed, but is usually mixed with disagreeable fetid muco-purulent blood-stained materials. About this stage of the disease the patient expectorates quantities of frothy mucus, and the secretions become more and more offensive. Alongside the development of dysphagia, it will be observed that the patient is rapidly emaciating and the blood becoming more and more deficient in colouring matter and in blood corpuscles. The emaciation is generally but not always marked. In the case of W. F—— (Case 3), even although he was practically unable to take any food for three weeks previous to admission, at the operation of gastrostomy there was fully three-quarters of an inch of fat covering the abdominal wall, and the portion of the omentum exposed was noticed to contain a considerable quantity of adipose tissue. The stomach was quite empty and collapsed. But while, in this particular case, the emaciation was not so marked as one would have expected under the circumstances, the condition of the pulse, the temperature, the feeling of extreme weakness, and the tendency to syncope all showed the effects of starvation.

In most of the cases which I have shown to you the patients have not complained much of hunger, except perhaps during the early stage of the disease. In the more advanced cases it is frequently very difficult to get food taken, even although the patient is able to partake of fluids or semi-fluid diet. Partly on account of the dryness of the throat and fetid odour of the breath, but also I believe from a desire that their suffering may soon terminate, the patients may absolutely refuse to take nourishment in any form. Some time ago I had a case where I was feeding the patient very satisfactorily by a stomach-tube, when one morning she intimated that she had had her last meal, and would allow no more food to be given to her in any form; but this was not to be wondered at, for after each meal she was tortured with severe pain in the epigastrium, due to the collection of large quantities of gas in the stomach, which she was unable to rid herself of. In very few of the cases which I have seen does the patient complain much of pain during deglutition, unless in those instances where the tumour is situated high up. In these the pain during swallowing is often sharp and burning, and is referred to the ears and side of the neck rather than to the throat. Between meals the pain is less severe, but still present at all times unless when relieved by treatment. When the disease attacks the middle third of the œsophagus the patient not uncommonly states that in the evening or during the night he experiences a feeling of a "load of uneasiness" or even of dull aching pain in the back or in the epigastrium. Should the carcinoma involve the lower end of the œsophagus, the patient seldom suffers from pain either during deglutition or at other times. This absence of suffering in such cases is somewhat remarkable. For example, in the case of H. C—— (Case 9), even although the carcinoma involved the lower extremity of the œsophagus and the cardiac end of the stomach, the patient, on being carefully questioned, stated that he suffered from pain in the stomach at no time since the onset of the disease. Respecting the sensation of the stomach, it is rather remarkable that simple ulceration should cause so much distress; while stitching of the stomach, or even perforating its walls with the electric cautery, as observed in the cases of W. F——, Mrs. C——, and W. H—— (Cases 3, 4, and 7), should hardly be felt by the patients. The presence of dyspnœa, aphonia, and cough depends upon the position of the tumour. When the upper part of the larynx is involved obstruction to breathing may be occasioned, as I have already shown, by direct pressure upon the air passages by extension of the tumour into the larynx, or by œdema, as in Case 4. Again, as a result of involvment of the recurrent laryngeal nerves, paralysis of the muscles of the larynx may be produced and give rise to aphonia or dyspnœa according to circumstances. The voice may also be impaired or lost as a consequence of the tumour invading the cavity of the larynx. Cough is a very common symptom, and may be caused in many ways—by saliva or food flowing into the larynx or trachea and there giving rise to catarrh, by the establishment of fistulous openings between the gullet and air passages, or by reflex irritation. Patients affected with carcinoma of the œsophagus, partly on account of their weak physical condition, are very liable to attacks of tracheal and bronchial catarrh, even although there may be no evidence to show that the malignant growth in the œsophagus is interfering with the function of the lungs. When the growth is situated in the first part of the œsophagus its situation and extent may be easily ascertained by palpating the neck or by examination with the finger passed into the pharynx. Should the disease attack the œsophagus at a lower level, in order to gain information it is often necessary to examine the passage by means of bougies. At the demonstrations I have shown you how these instruments

Digitized by Google

are used, so that in the remarks I am about to make I shall limit your attention to their employment only as applied to cases of stricture. When the bougie, one of large size to begin with, has been introduced into the œsophagus, it should be passed gently, no force being employed under any circumstances. If any obstruction be encountered in the course of the œsophagus, the bougie should be marked at the point in contact with the teeth, then withdrawn, and the distance from the point of the instrument to the mark carefully measured. The surgeon should then introduce a smaller instrument, and so on gradually going down the scale until he either succeeds in penetrating the stricture or in assuring himself that the obstruction is complete. In cases of cancer of the œsophagus sometimes even the most careful use of bougies may cause injury and slight hæmorrhage. In such instances the employment of instruments should be discontinued, but regarding this point I shall have more to say when we come to speak of treatment.

I have now completed what I have to say respecting the etiology, pathology, and diagnosis of carcinomatous disease of the gullet, and at the next lecture I will ask your attention to the other tumours which may occupy that canal, and also to spasmodic and organic stenosis.

THE BEARING OF RECENT BIOLOGICAL RESEARCHES ON THE PRACTICE OF MEDICINE AND SURGERY.

BY G. SIMS WOODHEAD, M.D., F.R.C.P.EDIN.,
DIRECTOR OF THE LABORATORIES OF THE ROYAL COLLEGES OF PHYSICIANS (LOND.) AND SURGEONS (ENG.).

(*Continued from page 13.*)

EVEN before the observations made by Beumer and Peiper it was well known that certain diseases, such as small-pox, could, when introduced into virgin soil, become excessively malignant, and it is recorded that whole tribes of North American Indians have been decimated and in some cases almost exterminated by this disease. Similarly it has been remarked that regiments that have been in certain barracks for a considerable length of time have been comparatively free from typhoid fever, although a sporadic case might occur; as soon, however, as a new regiment has marched into the vacated barracks typhoid fever has at once broken out as a widespread and most virulent disease. In both these cases it would appear that there is some process of acclimatisation, similar to that above mentioned, in all those who are exposed to the action of certain organisms or their products for any considerable length of time; whilst in those who for the first time come under the influence of these agents the power of special or general resistance is paralysed, and the patient succumbs. Coats[1] holds that this resistance is in different races the result of hereditary influence—that is, that we must look upon the process as due to a long-continued acclimatisation through successive generations. Coats, quoting Hirsch, points out, for instance, the remarkable difference as regards susceptibility of malarial fevers between negroes and Europeans, whilst the reverse is the case as regards susceptibility to small-pox. A number of similar examples of other diseases in which the same thing is seen are also given. All these examples are held by the followers of Metchnikoff to be in favour of the theory of phagocytosis; but, as we shall find it necessary to point out, several very strong, though not perfectly conclusive, arguments have been advanced in support of the theory put forward by Buchner and others of the German school, that immunity depends more on the soluble constituents of blood-serum than on the presence of phagocytes. Buchner maintains[2] that the cause of recovery of an animal from an attack of an infective disease is not due to the action of phagocytosis, but to the disinfecting action of the serum, and that phagocytosis is merely the result of an attempt on the part of the organism to get rid of the devitalised micro-organisms. He admits that phagocytosis occurs only in those cases in which an effort is made on the part of the organism towards recovery—i.e., that it occurs only where a certain immunity is present, but that it occupies merely a position of secondary importance, and that it is due to the action of chemotactic proteins which are set free from bacterial cells that have been rendered inert by the action of the serum. He had previously pointed out that certain proteid bodies introduced into the circulation exerted a very great effect on the leucocytes, which became enormously increased in number. The same thing had been previously observed by Schmidt of Dorpat and his pupils, and more recently it has been further worked out in connexion with Wooldridge's tissue fibrinogen by A. E. Wright and others. Buchner also points out that Roux and Metchnikoff, both of them believers in the importance of phagocytosis in relation to immunity, differ materially as to their interpretation of the effect of the action of the "specific toxines" of micro-organisms on leucocytes, Roux holding that these products attract leucocytes, exerting a positive chemotactic action, whilst Metchnikoff regards them as negatively chemotactic or as repelling the leucocytes. In order to get over this difficulty, Buchner suggests that it may be possible that certain toxines or toxalbumens may act positively and that others act negatively, but he admits that as yet we have no proof of such different action. Some time ago it was pointed out[3] that the same irritant, toxine or antiseptic, might act in different ways, according to its concentration, or according to the period during which it was allowed to act. Lister,[4] using a red-hot wire, which he gradually approached to a ciliated cell, found that when the wire came to a certain point it set up more rapid movements of the cilia, the heat acting as a stimulant by increasing the molecular activity in the cell. This was withdrawn, and again the speed of the movement fell. The hot iron was again brought near, and quickening was again produced, though not to such a marked extent. It was brought nearer still, and the motion now became slower and at last ceased. When the hot wire was suddenly brought near the stage of the microscope the ciliary movements stopped at once." Schulz,[5] working out the same idea from a different point of view, has been able to prove that the ferment power of yeast is distinctly increased by the addition, in sufficient dilution, of such virulent protoplasmic poisons as corrosive sublimate, arsenic, carbolic acid, and iodine; and he formulates the proposition that "every irritant exerts an action on every living cell of which the effect in relation to the cell activity is inversely proportional to its intensity." Wood and I repeated some of these experiments, and came to the conclusion that, as regards antiseptics and those protoplasmic poisons, there could be little doubt that just as in the case of sedatives, such as opium and chloroform, there is a stimulating stage through which the cells may become habituated by the continued and gradual increase of the dose to the action of the poison, so also was the stimulating or depressing action of an animal poison manifestly exhibited in cases of infectious disease. It has frequently been pointed out that when virulent anthrax is introduced into a susceptible animal no marked lesion is evident at the point of inoculation, but the animal dies rapidly of general anthrax; whilst if the same anthrax is introduced into an animal partially protected by vaccination or into an animal that is naturally refractory, or if it be introduced in sufficiently small quantity even into a susceptible species, there is usually a local reaction with inflammation, rarely accompanied by any general disease; so that here, as in the case of an abscess, the weakened poison acts upon the normal leucocytes or the strong poison acts upon the acclimatised leucocytes as a stimulant, and not as a depressant, with the result that the organisms and the disease are distinctly localised; the toxines are destroyed or eliminated, and although the local symptoms may be severe, there is no general disease. It is evident therefore that in the one case the poison acts as a stimulant, in the other as a depressant; or if we prefer it, the one exerts a positive, the other a negative, chemotactic action, for this is really what it amounts to.

Ruffer, in his experiments on the effect of antiseptics when introduced into the tissues in fragments of sponges, has arrived at very much the same conclusion, and he has

demonstrated in a most clear and satisfactory manner the chemotactic action of dilute solutions of such substances as corrosive sublimate, turpentine, and iodine.[6] When dilute solutions are used, the leucocytes from the surrounding tissue pass into the sponge in considerable numbers, and we have a regular zone of deeply stained cells advancing and getting rid of the foreign substance; whilst where the stronger solutions are used the leucocytes appear to be repelled or paralysed, and only when a considerable portion of the foreign substance has been removed in solution by the action of the fluids of the body are the leucocytes able to advance. Roux and Metchnikoff also suggest[7] that leucocytes may become accustomed to the presence of considerable quantities of toxines in those cases where there is acquired immunity, and they bring forward considerable evidence in support of their thesis. Buchner criticises their position, and points out that since in the case of vibrio metchnikovi the animals which are immune against the action of the vibrio itself still remain remarkably susceptible to the action of the toxines, unless the acclimatisation is brought about very gradually, we must suppose that the leucocytes only have acquired a tolerance of the poison. Improbable as this at first might appear, and indeed as Buchner maintains, we have a number of facts which indicate that it may actually take place, and that even after the leucocytes have become accustomed to the presence of considerable quantities of the toxines the nutrition of other tissues in the body will be so markedly interfered with that the animal may succumb. In this connexion it was pointed out as early as 1879 by Maffucci[8] that the products of the tubercle bacillus, or even sterilised cultures of that organism, when introduced subcutaneously into healthy fowls or guinea-pigs, produced a condition which he termed "marasmus." Emaciation and atrophy of the liver cells and of the cells of the spleen were brought about; whilst circulatory changes of such a grave nature were set up that there was marked congestion, not only of the spleen, but also of the lungs and kidney. Anyone who has worked with anthrax bacillus or the bacillus of blue pus must have remarked the same thing, for even when an animal has come through an attack of one of these diseases it often succumbs at a comparatively late stage—say, three weeks from the time of inoculation—when the organs, especially the secretory organs, are found to be in a state of fatty degeneration. Animals made immune from anthrax are notably very easily affected by changes of temperature, and a cold wave will frequently carry off a whole series of animals thus protected; whilst in the case of the blue pus bacillus the death from marasmus at a late stage of the disease, after the active bacilli have disappeared, is looked upon as occurring almost invariably. In all these cases, then, although the leucocytes, according to Metchnikoff, or the fluid constituents of the blood according to Baumgarten, Buchner, and others, may have become more resistant to the action of toxines, and are able to destroy and eliminate bacteria, the effects on the other tissues are so marked that they have undergone distinct degenerative changes, which here also are the result of over-work through over-stimulation by a more or less concentrated poison. There can be little doubt that in these cases, as in diphtheria where fatty degeneration, as pointed out by Roux and Yersin, is of such frequent occurrence, the changes are due to the products of the micro-organisms—some holding that these products are excreted; whilst others (amongst whom may be reckoned Maffucci, Philip, Buchner, and Mitchell-Prudden and Hodenpyl) maintain that the proteins of which the micro-organisms are composed are the cause of these changes, and that they can only occur after the organism has been killed by the serum and broken down by the phagocytes. From experiments made by Cartwright, Wood, and myself[9] I am convinced that some at any rate of these products are undoubtedly very intimately bound up with the protoplasm of the micro-organism, and can only be separated by a most careful treatment or long-continued maceration, especially after the organism has been killed. I shall return to this question of chemotaxis.

It has recently been maintained that micro-organisms are present in all the tissues of the body, and that if a healthy animal be killed these micro-organisms will develop, multiply, and set up decomposition of the tissues in which they are present. Mr. Lawson Tait[10] says, "A solid mass of beef—say, a bed and silverside—is removed from a perfectly healthy ox, and is put at once into a sound and healthy pickle. The pickle is a powerful antiseptic, and if the pickle reaches the middle of that beef before the germs contained in it have had time to start their work the beef in a few days or a week or two will be fit to eat; but every housekeeper knows perfectly well that the result will depend absolutely upon the outside temperature. It would be absolutely impossible to pickle a piece of beef in August which could be easily pickled at Christmas." And then he goes on to argue that during the few hours, or maybe few minutes, that the beef is exposed to the air it does not become impregnated with germs right to the centre; but that it is more consistent with common sense to believe that the germs were in it before it left the ox, and therefore in life. I have in connexion with this matter experimented most carefully with a view of determining whether in a healthy animal micro-organisms really find their way, or remain for any length of time capable of development and multiplication in the animal tissues. I have repeated the experiments made by Chiene and Ewart, Burdon Sanderson, Ballance and Shattock, and others, and I am convinced that in a healthy animal or in a healthy human being there are no organisms to be found, except in certain cavities of the body, directly continuous with the external world; and that, even in some of these cavities and passages, as Lister long ago pointed out, where the walls are in close apposition, micro-organisms cannot exist. In the urethra, for example, no organisms are found beyond the meatus urinarius externus until the patient dies. If, however, the blood of an exhausted animal, or of a patient who has just died from some disease, be examined, or if particles of the dead tissues of diseased animals be examined in the same way as tissues of the healthy animal were examined, organisms may undoubtedly be found. We must therefore assume that in these instances the barriers which under ordinary circumstances exist have been broken down, and the micro-organisms have made their way from the respiratory passage or from the alimentary canal into the circulation, and so to the weakened tissues by which they are not immediately killed off. This is a point of very great importance, for we know that in cases of pyæmia, where micro-organisms are undoubtedly present in certain parts of the circulation, or in cases of abscess formation where we cannot in all cases assume that the micro-organisms are as definitely localised as is the case in pyæmic abscesses, suppuration is set up at one or more points, whilst it is entirely absent from others. We must therefore assume that organisms introduced at one point, and into comparatively healthy tissues, are killed off; whilst organisms which make their way into less resistant, unhealthy, or weakened tissues can multiply and give rise to localised suppuration. Although this is undoubtedly true, we may accept it as proved that in most instances pyogenic or pathogenic organisms have little power of maintaining their full vitality during their passage through the protective epithelial and lymphoid cells of the alimentary canal, say, and that in most cases, even when there is actual disease, they are so far weakened that their destruction is ensured within a comparatively short time, even by the weakened agencies (whether they be phagocytic or biotoxic) which ordinarily interfere with their advance. In the case of an incised or contused wound, where a considerable mass of tissue is devitalised and where large quantities of serous fluid, which is not constantly brought into contact with living tissues, and to which new nutrient material cannot be brought, and from which excretory products cannot be removed, we have of course all the conditions necessary for the growth of micro-organisms, a growth which will go on most luxuriantly should any seed material be allowed to find its way to this prepared soil.

As Lister used to point out, if the two surfaces of an incised wound can be brought close together after the stoppage of bleeding and the serum has ceased to escape, the wound will heal without suppuration from the fact that any micro-organisms which might make their way into the wound from outside are immediately destroyed. In those cases, however, where a large quantity of organic or inorganic material in which micro-organisms are present has been introduced into the wound, the case is different, for here a large number of organisms are partially protected by the material along with which they are introduced; they are able to obtain such foothold that they cannot be got rid of without a determined battle between them and the phagocytes, as the result of which we have what is known as suppuration.

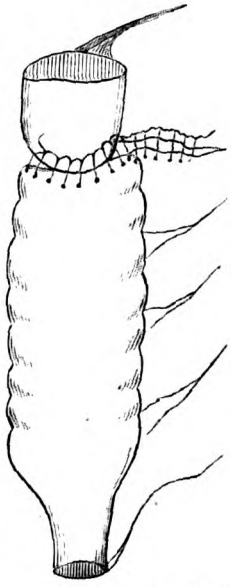
Whatever may be held as to the ultimate mechanism of immunity there can be little doubt that suppuration is most intimately associated with phagocytosis. If we take the case of an ordinary abscess it is usually found that chains or masses of cocci are found in the lymphatics, especially those in the connective tissue; whilst in the case of pyæmic abscesses, pyogenic micro-organisms become impacted in the small vessels. In either case the result is much the same, though where the organisms make their way by the bloodvessels they occur in larger masses, the process is more acute, and the abscesses are smaller; where they are conveyed by the lymphatics the masses of micrococci are smaller, though the immediate area of distribution may be wider than when the infection is by the bloodvessels; and more extensive localised suppuration ensues.

It may, perhaps, be said that abscesses have been so frequently described that it is superfluous to give any further description; but as I wish to insist upon one or two special points I shall give a short description of what may be seen in a small septic embolic abscess—in the muscle of the heart, say. In its centre may usually be seen a section of the vessel plugged with a mass of micrococci. This, when stained with one of the aniline colours, stands out very distinctly, especially as around it there is usually a very imperfectly stained zone of somewhat homogeneous tissue, which consists of the wall of the vessel along with fragments of muscle, amongst which lie a few unstained, and therefore probably dead or degenerated, leucocytes; the fragments of muscle fibre have also lost much of their ordinary typical structure and appearance. Outside this area comes a zone of multinucleated leucocytes, or, if we prefer to speak of them as such, phagocytes, deeply stained, evidently in a very active state of existence; whilst here and there is a larger cell with one, or rarely two, deeply stained nuclei, derived apparently from the fixed connective tissue cells. At the extreme margin of the abscess these fixed connective tissue cells are more numerous as they lie in this cellular mass, the muscle fibres are much degenerated, fragments of the sheath remaining, with here and there scraps of much degenerated or vacuolated granular muscular fibre. In this case there can be little doubt that the products of the micro-organisms acting on the tissues in their immediate neighbourhood have done one of two things—viz., they have lowered or destroyed the vitality of the protoplasm directly, or they have set up a kind of digestion of the muscular fibres and their tissues, a function which is usually ascribed specially to the leucocytes that are brought up at a certain period of the process; for following or accompanying this alteration in the muscles, which has resulted in such a degeneration that the nuclei within them are now imperfectly stained, there has been a further migration of leucocytes from the distended vessels in the degenerating area, which gradually make their way from the margin to the centre of the abscess, and digest and remove the degenerating tissues.

In this process a number of these leucocytes or phagocytes are destroyed and disintegrated either by over-stimulation or over-work, or possibly by the peptonising action of the micro-organisms or of the still active leucocytes; and pus cells—devitalised cells which can never return to the vessels—are formed. As the abscess increases in size more and more of the leucocytes in the centre of the abscess become disorganised; but those near the periphery are regularly reinforced, to form a barrier to the advance of the bacteria, either merely temporary or more permanent in character according to the original vitality of the tissues on the one hand, and the activity of the micro-organisms on the other; even in cases of acute abscesses, sooner or later localisation occurs almost invariably.

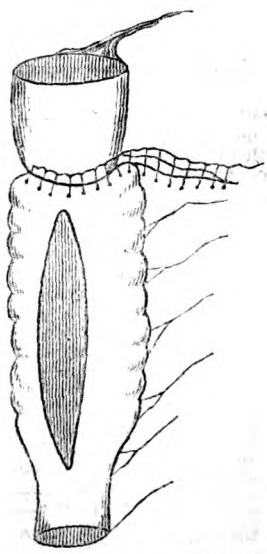
(To be continued.)



A SUGGESTION FOR THE TREATMENT OF IRREDUCIBLE INTUSSUSCEPTION OF THE BOWELS.

BY ARTHUR E. BARKER, F.R.C.S.,
SURGEON TO UNIVERSITY COLLEGE HOSPITAL, ETC.

IN the discussion which followed the reading on May 10th, 1887, of a paper which I had the honour to present to the Royal Medical and Chirurgical Society on a case of excision of an intussusception of the sigmoid flexure of the colon I was asked how I should deal with a case of intussusception in which the mass could not be reached from the rectum, and was found to be irreducible on opening the abdomen. My reply was that the possibility of such a state of things had occurred to me long ago, and that I had formulated an operation to meet the difficulty, but had not had as yet an opportunity of putting it into practice. I then described this procedure briefly to the meeting,[1] and now propose to publish it in detail in the hope that it may be the means of saving life in some cases belonging to a class hitherto regarded as almost hopeless. I have waited for more than five years for an opportunity of putting this method into practice in the living body, and testing its feasibleness and practical value. Having during the past summer been called upon to deal with two cases of irreducible intussusception, and having in each employed this procedure, the time appears to have arrived to make it more generally known, and to suggest its being tested by other surgeons. For, although in the cases in which I used this method it did not prevent a fatal termination, the attempt proved that the operation was quite feasible, and could be completed in a reasonable time and without much difficulty. It also showed, I think, that it was correct in principle, and that the fatal result was not due to any inherent defect in the procedure itself, but to the desperate condition of these particular cases. And I cannot help feeling that under less unfavourable conditions, and with an increased experience of details, this method will prove very successful.

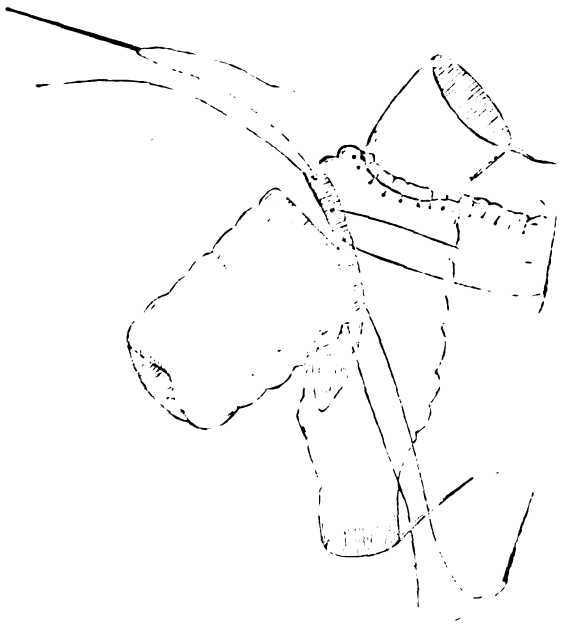


The procedure is as follows. Given a case of intussusception which cannot be reached from below, and which on opening the abdomen is found to be so tightly strangulated that reduction, even if feasible, could only end in disaster, then, instead of forming an artificial anus on the one hand, or, on the other, resecting the whole mass of damaged bowel directly, and suturing the divided ends together (both most formidable measures which have so far been followed almost invariably by death), I proceed as follows:—At the point at which the intussuscipiens receives the intussusceptum the two portions of the bowel are at once united by a continuous circular suture of fine silk taking up the serous and muscular coats of each, and carried on to the mesentery. (Fig 1.) A longitudinal incision is then made for about two inches through all the coat of the intussuscipiens on its free margin (Fig. 2). This gives access to the

FIG. 1.

First step: to join intussusceptum and intussuscipiens above by circular continuous suture.

FIG. 2.



Second step: to open intussuscipiens by longitudinal incision.

Digitized by Google

sausage-like intussusceptum within. The latter is then drawn out through this incision, and is cut across close to its upper end (Fig. 3); or, if too long to be first drawn out, it may be cut across *in situ*. A few stout

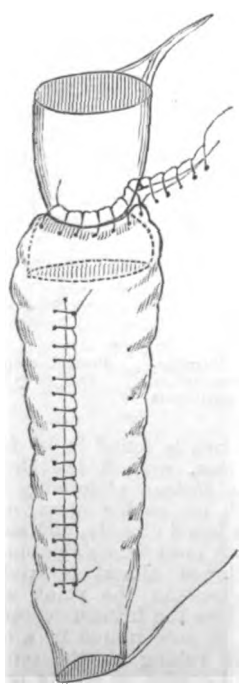

FIG. 3.

Third step: to draw out intussusceptum, cut it off, and suture its divided edges.

silk sutures are, however, passed through all the walls of the stump as the mass is gradually cut off (Fig. 3), and are tied tightly so as to keep the serous surfaces in contact and control all bleeding from the vessels entering it at its mesenteric attachment. The stump is now cleansed, dried,

FIG. 4.

Fourth step: to close longitudinal incision, leaving stump of intussusceptum inside.

and dusted with iodoform, and is allowed to drop back through the incision into the lumen of the intussuscipiens Then the longitudinal incision in the latter is closed by a continuous suture from end to end (Fig. 4). Toilet of the surrounding parts and closure of the abdominal wound completes the operation, which in my first case only lasted half an hour and in my second a little longer. In a future case I shall look forward to finishing the whole operation in a much shorter time and with much less manipulation. Now, in this operation the resulting junction of the bowel is just what we aim at in the far more elaborate procedure of direct resection of the bowel. But we have the great advantage, besides the saving of time, of not interfering with possible adhesions at the point of strangulation or with the mesentery. Moreover, the vessels of the latter are probably blocked by the strangulation at a point above that at which they are cut, and, if they are not so, they are closed by the same sutures which bring together the divided edges of the stump.

In both my cases the operation was practically extra-abdominal and was comparatively easy. The principle of the procedure is, as I pointed out in my first notice of it at the Royal Medical and Chirurgical Society, to imitate what nature does in those rare cases in which the intussusception is thrown off by gangrene. But by this method the part that would slough is boldly cut away without disturbing the adhesions which form round the upper end. Moreover, these adhesions are reinforced by sutures applied first on their proximal (Fig. 1) and then on their distal aspect (Fig. 3). My impression is that the sutures used for the divided surface of the intussusceptum will not require to be many. Three or four towards the mesenteric aspect, which will secure the vessels, will be, I think, enough.

CASE 1.—Arthur C——, aged four months, was brought to University College Hospital on July 31st, 1891, having had his bowels obstructed for three days The attack had begun on the 27th with violent pain and without any history of previous illness. A small motion had been passed on the 30th, but no flatus. The mucus and blood passed on admission had a gangrenous odour, and the finger introduced by the rectum came away covered with bloody mucus, with the same smell. An attempt to reduce the intussusception had been made by inflation before admission, but had failed. When brought to the hospital the child was very collapsed; pulse 140, extremities cold. Its abdomen was tense. Per rectum the intussusception could be reached about two inches from the anus. Under chloroform a sausage-shaped tumour was felt in the left iliac region. The bladder having been emptied, I opened the abdomen in the middle line, and found in it a quantity of dirty, grey, foul fluid. The intussusception was now drawn out of the abdomen, and immediately it was seen that the intussuscipiens was perforated by two gangrenous ulcers, from which the sloughing mucous membrane of the intussusceptum protruded. These ulcers were laid open into one, and through this the intussusceptum was withdrawn, cut off, and sutured, as described above, with four sutures The stump was then replaced, and the edges of the ulcerated intussuscipiens, being inverted, were drawn together with an ordinary continuous suture. Toilet of the surroundings and closure of the abdominal wound completed the operation, which had lasted half an hour. The child was put back into bed surrounded with hot bottles, but sank gradually, and died ten hours later. In this case little was to be expected from any operation, the abdomen having already been infected by gangrenous fluid and the child's powers being exhausted; but the subsequent necropsy showed that the suture of the bowel was quite firm, and resisted a high pressure of water without leaking. The lumen was also pervious through the stump of the intussusceptum. The portion excised contained part of the cæcum and the termination of the ileum.

CASE 2.—Raymond G——, aged twelve years, was admitted into University College Hospital on Aug. 14th, 1891. On Aug. 12th he was seized with sudden pain in the abdomen, which soon became tender and swelled up. He then took a dose of castor-oil; this was followed by a motion the same night "like diarrhœa." The next day another slimy motion was passed mixed with blood. He was sick twice during the day, but passed no flatus. On the 14th, before admission, he was again sick, but the pain was less, probably owing to the opium which had been given him by his doctor. On admission on the 14th (5 P.M.), there was no collapse. Pulse 116, rather small, and compressible. He was dark and sunken round the eyes, but quite sensible. The intussusception could be felt through the abdominal wall, but not per rectum. On opening the abdomen I was able to draw out the intussusception without much difficulty, and found it five or six inches long. The intussuscipiens was

Digitized by Google

very tightly stretched over the mass within, and was dark purple above. Hoping to be able to reduce this infolding as I have done successfully in other cases, I grasped the intussuscipiens below the swelling, and gradually squeezed it against the end of the intussusceptum. But very soon the damaged bowel began to give way over the upper part of the tumour, the serous coat tearing in one or two places transversely, and then the muscular coat. Finding that reduction was impossible, I now increased the amount of bowel intussuscepted until the tears in the serous coat were infolded, and then performed the operation described above and figured. In this case the incision was made longitudinally in the intussuscipiens. On cutting away the intussusceptum and suturing it the little finger could be passed through its lumen into the distended bowel above.

The most careful antiseptic precautions were of course taken in both these operations. The usual restoratives were used and morphia was given, but the patient's condition became gradually worse and he died fourteen hours after operation. The portion of bowel removed consisted entirely of jejunum. There was no adhesion between its serous coats which were separated by effused fluid.

Necropsy by Mr. WHITE.—"There is a slight trace of turbid fluid in both flanks and a few trifling adhesions between the coils. In the neighbourhood of the sutured intestine everything is quiet. The intussuscipiens for quite nine inches below the point sutured is livid and ecchymosed. The longitudinal line of suture in the intussuscipiens is perfectly satisfactory and hardly to be noticed, with a little plastic lymph about it. The intussusception was within three feet of the duodenum. Before opening the sutured bowel it was tied over a water tap, and the water was turned on. This passed freely through the sutured portion without leakage, and only when the distended force was made extreme by closure of the bowel below was there a trace of the latter. Both lines of suture appeared perfectly adequate. There was no hæmorrhage either inside or outside the bowel. The internal organs were all normal."

In this last case I believe I was very near success. But the condition of the bowel was very bad, and I lost time, besides, in fruitless attempts to reduce the intussusception. This only resulted in a cracking of its two outer coats, which were softened above. Had I at once proceeded to perform the operation described it is probable the result would have been different. But of course there are factors in all these internal strangulations which may have the most unfavourable influence upon the general condition without giving much evidence of their presence at the time of operation. These might have vitiated the operation, even if it had been more rapidly completed. It is satisfactory to note that as far as the suture was concerned it left nothing to be desired. And, besides this, the lumen of the bowel was now quite free. Again, one point about which I was very anxious was cleared up by these operations, specially by the latter—namely, the condition of the included portion of the mesentery and its vessels. Neither the mesentery itself nor its vessels gave any trouble. The first was found quite secure at its junction with the bowel, and its vessels were also perfectly controlled by the sutures which had been passed through the stump of the intussusception. It might be objected that, even if these patients had recovered after operation, they would have suffered from stricture of the intestine at the point sutured. This has certainly not been the case with two patients upon whom I performed excision of an intussusception of the sigmoid flexure of the colon, by a method almost perfectly analogous. One of these women is now in the enjoyment of excellent health without intestinal trouble, more than five years and a half after operation; the other I have lately seen in the street quite well, upon whom I operated last summer. I can already see some small points in which the details of the operation described above might perhaps be improved, and hope to be able to effect these improvements in subsequent cases.

NEW COTTAGE HOSPITAL AT LEDBURY.—The opening of the new cottage hospital took place at half-past twelve on the 29th ult. The hospital—which cost £3000—has been given to the town by Mr. M. Biddulph, M.P., in commemoration of the coming of age of his eldest son, Mr. John Biddulph.

PLEURAL EFFUSION AND EMPYEMA.

BY JAS. ALEX. LINDSAY, M.A., M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE BELFAST ROYAL HOSPITAL; CONSULTING PHYSICIAN, ULSTER HOSPITAL FOR WOMEN AND CHILDREN.

(Concluded from page 18.)

I PASS on to consider the second question which I have put down for discussion—viz., "Is the diagnosis of pleural effusion from pneumonic consolidation ever impossible?" There are some good clinical observers who teach that there are many cases, especially in children, where it is impossible to feel sure of the presence of fluid before inserting the needle, the physical signs being indistinguishable from those of pneumonic consolidation. This is no doubt a consolatory doctrine, but I think we should pause before assenting to a proposition which, however convenient to ourselves, is hardly flattering to the resources of our art. I am disposed to believe that cases in which the thorough application of the various methods of physical examination will leave a real doubt upon our minds are few in number, though I do not deny that now and again, though very rarely, a case presents itself in which the physical signs are puzzling and conflicting. In cases of doubt I am accustomed to rely mainly upon two signs, and I have very rarely found them to fail. Those two signs are (1) the diminution or absence of the normal vocal fremitus, and (2) the displacement of organs, especially the heart. The former of these, though not absolutely diagnostic, is certainly almost invariably found where fluid is present, and is excessively rare in any other condition. The displacement of organs, especially the heart, is diagnostic unless there are grounds for suspecting some other cause for it. I believe that attention to these two points, together with the careful mapping out of the area of dulness, will make the distinction between pleural effusion and pneumonic consolidation usually easy. The character of the breathing is not to be depended upon in doubtful cases. Bronchial breathing is quite common in pleurisy, and cannot be distinguished from the breathing of pneumonia. Nor is vocal resonance any help. The sound of the voice heard through fluid is quite variable, and may be normal, or simply faint, or bronchophonic or ægophony may be heard. The history of the case and the course of the temperature will usually afford some guidance. While, therefore, I believe the difficulty of distinguishing pleural effusion from pneumonic consolidation has been sometimes overstated, I have notes of a case in which great difficulty arose.

John B——, aged fifteen, was admitted to the Royal Hospital, under my care, on Monday, Dec. 9th, 1889. The history was that he had been taken ill on the previous Friday, Dec. 6th, with chills, headache, pains in the knees and the right side, and slight cough. He remained at work on Friday and Saturday, but gradually became worse, took to his bed on Sunday, and on Monday (1 P.M.) was removed to hospital. On examination I found the breathing hurried, respiration 44 to the minute, face flushed, temperature 102°. There was dulness over the base of the right lung, and in the right axillary region. Vocal fremitus was lost over this area, and the breath sounds were much diminished. The diagnosis of pleurisy with effusion seemed obvious. On Monday evening the temperature rose to 103°; herpes appeared upon the lips, and crepitus was heard at the right base. On the following morning (Tuesday, Dec. 10th) the temperature had fallen to 101·4°. The same evening, however, it rose to 104·2°; loud tubular breathing was heard at the right base, the respiration was 36, pulse 116, and there was cough, but no expectoration. The patient was not obviously worse. He had a quiet night and slept well. On the following morning (Wednesday, Dec. 11th) the tubular breathing had quite disappeared, the breath sounds were almost absent over the affected area, but some crepitus was heard at the upper level of the dulness; vocal fremitus much diminished, as before; temperature 102°; the pain in the chest had disappeared. The temperature on Wednesday night was 103°, but had fallen to 101° on Thursday morning. The pulse was now 100; respiration 48. The temperature on Thursday evening rose to 102·4°. On Friday morning it was 101°. Dulness and diminished fremitus as before;

Digitized by Google

some crepitations still heard over the affected area. A slight displacement of the apex of the heart was now for the first time observable. I inserted the hypodermic needle, and drew off a drachm of pure serum. The subsequent progress of the case presented the ordinary features of pleurisy, friction appeared speedily, and the boy was discharged well on Jan. 4th, 1890, having been in hospital twenty-six days.

To discuss this case adequately would take more time than I can afford for it. My conviction is that the case was one of pleurisy throughout, and that there was no pneumonia; but it will be admitted that the physical signs, the high temperature, and the labial herpes caused considerable difficulty. My reasons for regarding the case as one of simple pleurisy are as follows: 1. The onset was gradual, the patient not taking to bed until the third day. 2. The maximum temperature (104·2°), though high for pleurisy, was not reached until the fifth day of the disease. 3 The subsequent course of the temperature was irregular, and there was no crisis. 4. Vocal fremitus was much reduced or absent throughout. 5. The bronchial breathing lasted only one day, and was suddenly succeeded by almost total loss of the vesicular murmur. 6. The displacement of the heart was observable on the eighth day of the illness.

A few words must suffice for the third and fourth questions which I have put down for discussion. By a bloody effusion I mean not an effusion which consists of serum streaked with blood, which is not uncommon and of no particular significance, but an effusion which is mainly composed of blood. This has not been very common in my experience, though it cannot be reckoned a rare occurrence. I have met with it in three cases. In the first the patient died suddenly, and a post-mortem examination revealed the presence of an aneurysm of the aorta, of which there had been no characteristic signs during life. The second case was a very chronic one; but no tubercular, cancerous, or other complication could be detected. This case has been lost sight of, and I cannot say what is the explanation of the bloody effusion. The third case is still in progress, and there are some grounds for fearing tuberculosis. A bloody effusion is also known to occur in cancer of the pleura and in scurvy; but I have no personal experience of such cases. My cases are too few to warrant any conclusion, but so far as they go they corroborate the general impression that a bloody effusion is unfavourable and frequently conceals some complication. At the same time we must recollect that there are cases on record where the removal of a bloody effusion by aspiration has been followed by a speedy and uninterrupted recovery.

The answer to my fourth question—viz., "Can the presence of pus be positively diagnosed before aspiration?" must be a decided negative. The presence of pus may often be shrewdly suspected, but I have seen cases which have convinced me that the signs laid down in many text-books as diagnostic of the presence of pus are fallacious. If we trust to constitutional signs we are apt both to diagnose pus when it is absent and to overlook it when it is present. In one of my cases there was the most typical hectic fever, with high and remitting temperature, profuse night sweating, malar flush, and wasting; yet on aspiration the fluid proved to be limpid serum. In another of my cases there was only a very trifling rise of temperature, no night sweats or other symptom of hectic fever; yet the fluid proved to be pus. As regards the local signs, which have been alleged to furnish a *differentia* between serum and pus, I can only say that in none of my cases have I found them of any value. I should therefore be disposed to say that our wisest course at present is to admit that we cannot determine the character of the fluid present without removing some of it for examination, and that, where the distinction is of importance, we should determine the point at once by inserting the needle.

My fifth question—viz., "What is the best method of treatment for cases of moderate serous effusion?"—will require fuller consideration. It is to be regretted that we have no satisfactory records to show us what is the normal course of cases of moderate effusion without treatment. The tendency is, no doubt, to spontaneous subsidence, and the only practical question is whether by the administration of drugs or operative interference we can materially hasten the natural process. It is now generally admitted that many of the methods of elimination formerly in favour are either useless or injurious. The administration of diaphoretics, diuretics, and hydragogue purgatives would seem to exercise slight influence over the effusion, and in view of the facts that pleurisy is always accompanied by a good deal of debility and that a considerable number of cases become tubercular, depletory measures should not be pushed too far. Two remedies, however, maintain their position—viz., counter-irritation either by cantharides or iodine, and the administration of iodide of potassium. My experience would incline me to think that both these remedies are helpful, and tend to promote absorption. The addition of the ammonio-citrate of iron to the iodide of potassium seems often very advantageous, especially if the case tends to become chronic. The great question, however, in this connexion is whether aspiration should be performed, and, if so, how soon. In certain cases the necessity and advantage of aspiration are universally admitted. If the amount of the effusion be very large and dulness extend as high as the second rib in front, or if the measurement of the affected side be markedly increased, or if there be much dyspnœa, in such cases there can be little doubt we ought to perform aspiration without delay. The difficulty of decision is rather in that large group of cases where the effusion is moderate in amount and where there is very little dyspnœa or other disquieting symptom. The questions arise with regard to such cases: (1) Does aspiration lessen the chance of a fatal issue? and (2) Does aspiration shorten the duration of the disease? The first question may be dismissed, as a fatal issue in such instances is so rare that it is hardly a factor in the case. The second question is a very interesting one, but the difficulty of determining it is very great. I have collected a considerable amount of evidence, both from my own practice and from other sources, with a view of determining whether (in the class of case now under consideration) aspiration hastens recovery; but I find it impossible to draw any secure conclusions. One practitioner inclines to tap frequently and to tap early, and his statistics will be very favourable to aspiration. Another reserves tapping for serious cases with large effusion, or for chronic or semi-chronic cases, and his statistics will be unfavourable. My own experience inclines me to the view that, apart from urgent symptoms or excessive effusion, there is no advantage in tapping during the first fortnight, the fluid accumulating again and again if the tappings be repeated. If, however, the third week progresses without some decided evidence that the fluid is ebbing, or if at this period there is any increase of the effusion, tapping should probably be performed. One way to throw some light on this question would be to compare the best results obtained with and without tapping. I find that there is very little difference to be observed. Several of my cases in which tapping was not performed were convalescent in three weeks, and I have no evidence that tapped cases run a less course than this. Nevertheless, the good effects of tapping in suitable cases are often very striking.

I have, lastly, to consider some points in connexion with the very interesting subject of empyema. Of (*a*) simple aspiration for empyema I have no experience. It almost invariably fails, and there are many grave reasons against the delay which repeated tappings involve. Nevertheless, a success is occasionally obtained. A case has been recently reported to me by a medical friend of a young lady the subject of empyema whose relatives refused to sanction the operation of incision. Tapping was therefore resorted to, and after four aspirations there was no further accumulation of pus, and a cure was effected. Such a happy result is, we must remember, exceedingly rare. The plan of (*b*) continuous syphon drainage after the method of Dr. Bulau of Hamburg has won great favour in Germany, and has been most favourably reported on by Professor Leyden of Berlin and Professor Immerman of Basle. It consists in the use of an elastic tube connected with a trocar leading into an antiseptic solution. It is said to be unsuitable for cases of inexpansile lung, pyo-pneumothorax, and pulmonary fistula, as well as for those where the pus is thick. It is said to be somewhat difficult of application, as it requires perfect rest on the part of the patient, the elastic tube being apt to slip from the wound. Forty-nine complete cures out of fifty-seven cases with three deaths have been reported by this method, and this result must be regarded as highly favourable. Of (*c*) free incision, with or without resection of the ribs, I can speak very highly. It is the recognised operation in this country, and the results are most gratifying. Probably not less than four-fifths of the

Digitized by Google

cases thus operated on recover, provided there be neither tubercle nor amyloid disease present. My own experience is limited to three patients, all of whom made a good recovery. In one case dangerous collapse followed the operation, and the patient was only rallied by the most energetic measures. Resection of the ribs is frequently an absolute necessity from the manner in which the ribs get wedged down one upon the other. I have seen one case where the space between the ribs at the inferior angle of the scapula was barely sufficient to admit the edge of a knife. I am disposed to think that in all cases a very free incision is desirable, and that a thoroughly free exit for the pus should be secured at all hazards. I see no advantage in the plan of making two openings, which is a favourite method at some hospitals. As regards (*e*) irrigation, the present feeling is against its employment. Accidents have been reported from this procedure, and unless in cases of very foul pus, no advantage seems to accrue from it.

THE PERCENTAGE OF FIBRIN IN THE BLOOD OF LEPERS.

BY BEAVEN RAKE, M.D. LOND.,
MEDICAL SUPERINTENDENT OF THE TRINIDAD LEPER ASYLUM.

THIS inquiry was made in Trinidad, and was suggested by a case which occurred there. On opening the body of an anæsthetic leper a thoracic aneurysm was found which had undergone spontaneous cure.[1] The blood in leprosy was examined many years ago. Danielssen and Boeck[2] made fourteen analyses—eight in tuberculated and six in anæsthetic lepers,—and found the highest percentage of fibrin to be 0·6 per cent., and the lowest 0·22 per cent. Hillairet[3] also made three analyses of blood in cases of tuberculated leprosy, and found that the percentage of fibrin ranged from 0·31 to 0·61.

We cannot now accept the theory of Danielssen and Boeck, that the excess of fibrin and albumen in the blood is the primary cause of the other leprous changes. An examination of leper blood is, however, not without interest; for though there is reason to believe that leprosy is due to a bacillus, the changes which are produced in the blood, either directly or indirectly, are of no little importance. Thus the rapidity with which leprous tissues heal after operation is well known to those in charge of asylums, and has already been referred to by the writer.[4] Also the spontaneous formation of firm laminated clot in an aneurysm of the arch of the aorta is unfortunately by no means common. Another noteworthy fact was the rapid coagulation of blood in an anæsthetic leper, in whom the great toe was being explored for dead bone in the Trinidad Asylum. The blood clotted so quickly that it fell in round beads into the basin of water above which the operation was being performed. These beads remained undissolved in the water. The percentage of fibrin in this patient was afterwards found to be 1·25. It seemed, therefore, that an attempt to estimate the fibrin in leprosy extended over a number of subjects might not be without value. For this purpose fifty lepers were chosen from those in the asylum. An endeavour was made to obtain a nearly equal number of persons suffering from each of the three forms of leprosy, but otherwise they were chosen without selection, the blood being chiefly collected from operation cases. In these there is the fallacy that in cases of sinus or ulcer there may be a certain amount of local inflammation causing effusion of fibrin factors in the tissues. As far as possible this source of error was avoided by collecting the blood in such cases after the first gush had taken place. In each case the blood was collected in a test tube and immediately whipped with a rough piece of wood to collect the fibrin. The test tube, wood, and blood were then weighed together. The clot was afterwards detached from the piece of wood, left to soak for some hours to detach blood-corpuscles, dried on blotting-paper, and weighed. The test tube and wood were also washed, dried, and weighed, their weights being deducted from the original total weight. The remainder gave the weight of the blood, and that of the dried fibrin being also known, the percentage was easily calculated.

The accompanying table shows that the range of percentages obtained by this method was very great, the lowest percentage being 0·12, the highest 1·87. The blood in this

Table showing Percentages of Fibrin in Fifty Observations.

No.	Age. M.	Age. F.	Form of leprosy.	Time affected.	Percentage of fibrin.	Source of blood.
1	21	—	M.	17	0·56	Enlarged left mamma.
2	—	57	A.	12	1·07	Perforating ulcer of foot.
3	18	—	T.	9	0·66	Large tubercle of hand.

19	21	—	M.	4	0·95	Tuberculated thickening of finger.
20	45	—	A.	9	0·43	Sinus of foot.
21	—	16	T.	1	1·47	Tubercle of face and tissues at elbow.
22	22	—	A.	7	0·49	Sinus of great toe.
23	—	16	T.	6	0·30	Ulcerating tubercles of foot.
24	—	48	A	4	0·52	Sinus of finger.
25	41	—	A.	12	1·05	Ulcer of foot.
26	45	—	M.	1	0·12	Tissues in front of forearm.
27	32	—	A.	7	0·77	Sinus of foot.
28	42	—	A.	8	0·73	Sinus of finger.
29	37	—	A.	14	0·81	Ulcer of sole.
30	35	—	A.	8	1·25	Sinus of foot.
31	44	—	A.	7	1·06	Swelling of finger from necrosis.
32	42	—	A.	5	0·48	Swelling of finger from necrosis.
33	39	—	M.	2	0·19	Sinus of foot.
34	30	—	M.	6	0·41	Sinus of foot.
35	52	—	T.	5	0·29	Swelling of foot.
36	20	—	M.	7	0·82	Swelling of finger.
37	—	41	T.	2	0·69	Exuberant granulation of foot.
38	52	—	M.	1	0·25	Tubercles of face.
39	—	41	T.	3	0·68	Sinus of great toe.
40	—	21	T.	8	0·69	Tuberculated thickening of hand.
41	18	—	T.	1	1·00	Tubercles of nose.
42	56	—	M.	18	1·56	Tuberculated thickening of hand.
43	37	—	M.	5	1·31	Sinus of toe.
44	11	—	T.	2	0·41	Swelling of ball of toe.
45	36	—	T.	11	0·63	Tissues in front of forearm.
46	—	14	T.	1	0·50	Tissues in front of forearm.
47	41	—	M.	4	0·83	Infiltrated tissue of leg and foot.
48	57	—	M.	11	0·79	Ulcer of toe.
49	45	—	T.	10	1·87	Ulcer of leg.
50	41	—	M.	5	1·09	Swelling of leg.

Average percentage of fibrin in 16 tuberculated lepers	0·78
,, ,, ,, 21 anæsthetic ,,	0·79
,, ,, ,, 13 mixed ,,	0·72
Average percentage for the 50 observations	0·76

case, however, was collected from an incision at the side of a large hæmorrhagic ulcer of the leg, so that there was a possibility of the existence of the fallacy above noted. Taking, however, the average in the three forms of leprosy, there was seen to be a remarkable constancy in the percentage of fibrin. Thus in sixteen tuberculated cases the mean percentage was 0·78, in twenty-one anæsthetic cases it was 0·79, and in thirteen mixed cases it was 0·72. The mean percentage in the fifty lepers amounted to 0·76. In Danielssen and Boeck's fourteen observations the average percentage of fibrin was 0·36, while in Hillairet's three observations it was 0·65. Allowing, therefore, for the errors of experiment already mentioned, the mean percentage calculated on an increased number of observations and subjects agreed approximately with the results previously obtained from more limited records. The table contains details of the observations. It is noteworthy that in only two of the fifty cases was the percentage of fibrin below 0·2—the quantity said to be present in healthy human blood.

CANCERS IN UNUSUAL SITUATIONS.

BY CHARLES STEELE, M.D., F.R.C.S.

CASE 1. *Scirrhus of Tonsil.*—Mr. H. N——, aged fifty-five, consulted me in February, 1886, concerning his left tonsil, which felt full and uncomfortable. I had attended members of his family for several years, but he had never required medical attendance during that time; in fact, he was a remarkably healthy gentleman, of a cheerful, bright nature, and took a great deal of walking exercise. The tonsil was enlarged, having a smooth flat surface as large as a penny curling over on its anterior edge, very firm to the touch. There was also a visible fulness under the ear. I entered it "malignant?" in my notes. He turned to me and said, "Tell me, is it cancer?" I asked what should make him think so, and he replied, "Because my father died of cancer." I told him that I should wish to try absorbent but non-irritating treatment before arriving at a definite conclusion, but that its nature was questionable. He had some round red spots on his forehead, and frankly owned to chancre in early manhood, and his mind was relieved by the idea of treatment bearing upon that basis being adopted. The spots cleared away, but the tonsil remained unaltered for a month. This treatment was discontinued because the swelling under the ear started rapid growth, extending both in circumference and also outwards beyond the level of the ear. Swallowing gradually became difficult; he refused to go out of doors, lost flesh and appetite, and was reduced to a fluid diet. The tonsil did not enlarge much more, but the curled edge became more prominent. Development of disease was in the soft parts outwards. Large veins showed themselves, the mass extended backwards almost to the nape of the neck, the growth extended two inches beyond the level of the ear, dark, hard prominences formed; and eventually ulceration took place exactly as in a scirrhous breast. Sloughing took place, leaving a wide deep cup, in which hæmorrhages, at first slight, but eventually severe and sometimes arterial, occurred, but were checked by the local application of perchloride of iron, while other styptics failed. He became confined to his bed, and died in September. The medicine which gave him *relief*, and which he took for some months, was tincture of hydrastis, in one-minim doses three times a day. When I increased the dose to ten or even five drops he refused to take it, and would fall back on the minim doses. The fulness of the tonsil was what he first noticed in January, then the swelling under the ear; but he put off calling to see me in consequence of his dread of being confirmed in his impression that the disease was really cancer. Yet he was imperative as to a frank reply to question, and, when the specific course of treatment failed to make an impression, I was obliged to confirm his fear. Dr. Greig Smith saw him early in consultation with me, and we were perfectly agreed that the idea of removal could not be entertained, on account of the extension into surrounding parts and involvement of bloodvessels and nerves. Duration of disease nine months.

CASE 2. *Scirrhus of the Vagina.*—Mrs. K——, a widow, aged forty-six, consulted me in October, 1889, on account of discomfort in the lower part of the abdomen and slight vaginal discharge. She had two children, aged seventeen and eighteen, and had not ceased to menstruate. Although she looked healthy and in good condition, indications made me desire an examination, to which she demurred, considering that she was suffering from leucorrhœa only; but on my representing that it was absolutely necessary, she consented. I found the vagina to consist of a flattened tube of dense tissue, which felt like cartilage. Both bleeding and pain resulted even upon my turning my finger gently. There was a small nodule on the os uteri. The growth at that time did not extend in front to the meatus urinarius; micturition was natural. Little increase occurred for a month, then extension on the right side into the pelvis took place, producing neuralgia in the right anterior crural nerve, then lameness, and swelling below Poupart's ligament. Continuous pain set in, accompanied by feverish constitutional disturbance, and dryness and redness of the tongue; and a cold abscess gradually formed and extended from the trochanter major to the adductor brevis, and rendered by its internal influence regular catheterism necessary. Great relief was afforded by my drawing off the pus with a trocar, and natural micturition was restored. Restlessness and sleeplessness rendered a sedative necessary, and sulphonal suited her well until her death, which occurred in May. It was not until the fourth day that I could gain consent to make a post-mortem examination, and the weather being hot, decomposition had commenced. I took out the vagina, uterus, and appendages, with the involved surrounding parts, and found the vagina hypertrophied uniformly except at the right side, where the disease had extended and embraced the anterior crural nerve. The uterus had one small nodule on the anterior lip and another more recent one in the fundus. The ovaries were free. The specimens were too decomposed to show anything by microscopic examination, though submitted to it at once. This disease clearly commenced in the vagina, and the uterine deposits were secondary. The abscess being manifestly caused by pressure on the anterior crural nerve is a confirmation of the dictum that abscesses are caused by depressed nervous function. Known duration of disease nine months.

CASE 3. *Cancer of the Meatus Urinarius.*—Five years ago a gentleman who consulted me several times from a distance told me that his wife's health caused him much anxiety; that she frequently passed blood, but would not hear of her medical attendant examining her properly. A few months afterwards they came to reside here, and I was asked to visit the lady, aged sixty. I represented to her that an examination was essentially necessary, and that, if the cause of her hæmorrhage was a serious one, delay might render her case hopeless. She consented, and immediately my finger entered the vulva it impinged upon a mass of cancerous excrescence, which surrounded the meatus urinarius and extended backwards to half an inch from the bladder. I urged immediate removal while I could get beyond the disease and save the sphincter of the bladder. Both the husband and wife consented, and I removed the mass entirely with the écraseur, leaving nothing but sound tissue beyond. The case did well. For a time urine was passed through a retained indiarubber catheter, but this was removed as soon as cicatrisation was sufficiently established. Power of retention was gradually gained, except that when the patient sat in a perfectly upright position a little urine was always voided. She has remained free from any recurrence ever since. During convalescence this case was complicated by the gradual formation of an abscess on the front of the leg, half way between the knee and ankle, which was opened, and did well. The disease was epithelioma.

Clifton.

A RARE FORM OF SKIN ERUPTION.

BY H. R. KENWOOD, M.B., L.R.C.P., D.P.H.

AN extremely interesting case of an aberrant form of urticaria has been under my supervision for some years, and it serves to sustain in a striking manner the now generally accepted theory that this disorder is due primarily to a direct or reflex irritation of the peripheral vaso-motor system, in which contraction, followed by a partial paralytic dilatation of the cutaneous vessels, determines the exudation of lymph with the production of wheals. It must be held, however, that each sufferer from the complaint possesses a hyper-sensitive condition of the vaso-motor system, so that more or less trivial causes will suffice to disturb its balance. A severe body-chill has always furnished the exciting cause in this case, and after careful and thorough investigations the most absolute negative evidence of any concomitant derangement, either of the digestive, nervous, or reproductive systems, has been forthcoming. The urine has, however, always had its colour and acidity somewhat accentuated, but there has been no albuminuria or lithuria. The patient, who is now twenty-five, first noticed "swellings" when between seventeen and eighteen years of age, and they have since recurred on almost every occasion upon which she has caught a violent chill. She has always enjoyed excellent health and is of a slightly florid complexion. The eruption mainly consists of wheals, which are sometimes six inches in diameter, and are generally discovered on the third day after the chill (that is to say, when the other effects of "the cold" have somewhat spent themselves). These may occur anywhere about the body; the lips and eyelids (especially the lower) are frequently attacked, and the pharynx is said to have been

involved on an occasion during which I did not see her. Over the area on which a wheal is about to form the following sequence of events has been invariably noticed by both the patient and myself. The area at first suddenly assumes a slight red blush, sometimes bright like erythema, but generally of a somewhat duskier hue, and at this stage a faint "tingling" pain manifests itself. When the spot is rubbed by the patient or myself—and in all other cases the necessary friction or pressure is doubtless given by clothes, &c.—the centre rises, becomes blanched (relatively), and then extends rapidly by an indefinite border until it reaches the limits of its extension, by which time a faint red line is seen to surround a paler swelling. The tingling sensation is at all times slight, is greatest in the stage immediately preceding the swelling, and then diminishes, to disappear entirely when the wheal has reached its maximum development. At this later stage there are no subjective sensations of any kind which would tell her of their presence so long as she remains at rest, and does not rub or press them. The swellings last in bad attacks two days; but they have come and gone in two hours, leaving in no case any trace whatever of their existence, and we have both succeeded in some cases, but only early in the attacks, in producing wheals by friction over areas which have appeared perfectly normal. Apart from the slight discomfort accompanying "the cold," the patient feels perfectly well and in good spirits.

What marks the case as one of exceptional interest, however, is the fact that some of the swellings have frequently assumed the characters of a condition which has been described (by Quincke and Rapin notably) as "acute circumscribed cutaneous œdema"—that is, there have been present, I may say in *most* attacks—three or four on an average—œdematous tumefactions of the skin and subjacent tissue, of firm and knobby consistence, with ill-defined borders, and possessing a slightly pale hue relatively to the adjacent skin; which tumours pit (almost imperceptibly, it is so slight), upon pressure. Their favourite sites are the skin over the deltoid muscle of the arm and that over the region of the buttocks. The swelling of the tongue which accompanied a recent attack was due to one of them. They have never been, in any case which I have had the opportunity of investigating personally, less than two inches and a half in their longest diameter, and have generally shown a tendency to assume an oval shape. The largest had a diameter of over six inches, and was situated upon the buttocks, with its centre over the tuber ischii. Their near relation to the urticarial wheal is manifest from the closely similar sequence of changes during their development; from the almost equal rapidity in which they appear and disappear, and from the fact that in this case a common cause induces both to appear. As in the wheal there is at first a blushing of the area, followed by rapid swelling, which quickly spreads the while it grows paler and becomes eventually surrounded by a slightly—very slightly—reddened zone of skin. The borders of these hard swellings are not well-defined, and almost evanesce into the adjacent skin, and there are no subjective symptoms accompanying them when matured, not even one of tension.

How unlike typical acute urticaria the condition is, even if the presence of the hard tumours be excluded, is at once manifest from the absence of all evidence of any, even faint, constitutional disturbances of the nature which generally accompany that condition; the number and size of the wheals, many of which quite reach in the latter respect the proportions found in "urticaria gigans"; the seasonal prevalence of the disorder, most marked in the winter, whereas in acute urticaria by far the greatest incidence of attack falls in the spring and summer; the extreme faintness of all subjective sensations, and their total absence after the swellings have formed; while in acute urticaria the itching, tingling, and pricking sensations generally occur *with* the eruption, in a marked degree, and there is a craving to scratch. The case appears to me to be a hybrid of three conditions: (1) Common acute urticaria, (2) urticaria gigans, and (3) acute circumscribed cutaneous œdema. The patient has felt slight, obscure, and wandering muscular discomfort at times, which may be attributed to chronic rheumatism, though she has never had acute rheumatism, nor is there any parental history of the disease. She is somewhat of the "rheumatic constitution." Although for a time I was inclined to think that drop doses of aconite hourly exercised the greatest influence in limiting the duration of the rash (even more so than the salicylate of sodium of which I had read), I have since had ground to believe that a mixture of the latter salt with iodide of potassium has been more successful. It is difficult, however, to say anything definite upon the results of different treatments, as the duration of the condition, in spite of drugs, would appear in this case to bear a direct relation to the magnitude of the exciting cause; that is to say, it is the severity of the chill—a difficult factor to reckon with—which chiefly determines the severity and persistence of the condition, and therefore in different attacks it is impossible to tell what their duration would be apart from the treatment employed.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF ILEO-CÆCAL INTUSSUSCEPTION IN A MALE INFANT AGED NINE MONTHS.

BY T. CUMING ASKIN, M.D.

A SHORT account of this case may prove interesting, as the diagnosis was verified by a necropsy. A strong, well-developed male child enjoyed perfect health till the morning of Dec. 4th, 1891, when, while crawling on the floor, he was suddenly seized with great pain, which made him cry out. His mother said the bowels moved soon after, and the motion contained nothing but blood. The pain did not recur, but the child seemed heavy and stupid, and vomiting set in, nothing being retained on the stomach. I saw the child on Sunday evening, the 6th. His face had a pained and anxious expression. Surface of body cold. Temperature 98° in axilla; pulse about 160. Eyes dull, pupils dilated. Abdomen not distended. In the right iliac fossa a tumour, doughy in consistence and freely movable, could be easily and distinctly felt. Palpation did not seem to cause pain. A glycerine suppository was given and brought away a little blood. Bowels had not acted since the 4th. On the morning of the 7th I again saw the child, whose condition then was much the same as it had been on the previous day, except that he seemed weaker. The tumour did not appear to have altered much in position or size, and there was no abdominal tenderness or distension. I advised an operation, but the mother would not consent. I then sent for a pair of bellows, intending to inject air into the bowel, but the child died before they could be procured. The cottage was situated in a very lonely and isolated part of the county, being several miles from any village or town.

The necropsy revealed an ileo-cæcal invagination, about four inches of the gut being involved. The intestine was intensely congested, and I had considerable difficulty in withdrawing the invaginated portion of the gut. The small intestine was moderately distended (this must have occurred within a very short period of death). There was no evidence of general peritonitis.

Alderton, Suffolk.

CASE OF APHASIA.

BY D. ROBERTSON DODIE, M.D. EDIN.

THE following case may prove of interest to medical practitioners and merit insertion in the columns of THE LANCET. By publishing I invite a free discussion of the case, and will leave it to more experienced and intelligent observers to explain how the favourable termination which I now describe came about.

Mrs. H——, aged fifty-six, was suddenly seized with loss of speech, unaccompanied by any paralysis, in January, 1883. I did not at that time see the patient, but I am well aware that she lost her speech completely, and could not utter a syllable. She could read quietly to herself, but was unable to communicate her ideas in writing. She was treated in a most careful manner by a neighbouring practitioner, and was soon up and attending to her household duties. I frequently attended Mrs. H—— when she came into my district during 1883, and subsequently for minor ailments in connexion with the menopause, and I am inclined to think

Digitized by Google

this had something to do with the seizure. An embolism might be formed in the uterine sinuses and carried onwards to the brain. This is a mere speculative opinion. She could say nothing but "ta-ta" and "tut-tut" from 1883 to 1891, and by signs and gestures lead her husband and family to understand what she wanted. My patient subsequently removed out of my district, and I never heard of her until last month, when she came to consult me and to report the marvellous change which had come about in the following way. On Saturday, Oct. 31st, 1891, she was thrown into a violent passion and much annoyed by her daughter, with whom at times she does not get on very well, and the strife lasted a considerable time. After the storm had blown over she felt a severe pain in the head, and after a short interval she found she could speak perfectly well and give expression to her feelings as plainly as ever she did in her life. As was to be expected, the sudden change caused great consternation in her household and struck terror into the hearts of her neighbours. I had a long conversation with my patient a fortnight after the occurrence, and was most interested in her story. She is an intelligent woman and for nine years had been unable to give utterance to her thoughts. I have recorded this case at some length because I believe it to be unique, and so far as I can learn no such sudden and complete restoration of speech after so long a period of silence has ever before been recorded.

Coldstream, N.B.

SOFT PAPILLOMA OF EAR OF SUSPECTED INFECTIOUS ORIGIN.

By ROBERT LAKE, F.R.C.S.

NEW growths of the external ear are, when compared with other affections of that part, somewhat uncommon; thus there did not occur more than a single case, and that not correctly speaking a growth, in 1146 consecutive cases in the aural department of St. Thomas's Hospital.[1] The general position of the one described below is the usual seat of the soft variety of papillomas,[2] the hard ones being also found in other situations.

The patient, a girl of short stature, aged seventeen, of dull appearance, had been subject to ostitis media purulenta for two or three years; no cause was known for its having originated. For some weeks there had been severe pain in the ear; the discharge was most horribly offensive. On examination of the affected ear (right), the meatus was found closed by three pinkish masses, which were at first believed to be purulent collections in the subcutaneous tissue. One mass covered the posterior surface of the tragus up to the entrance to the canal; the next one sprang from the inner surface of the antitragus; the third and largest, fully half an inch across, grew in that part of the concha adjacent to the canal, proceeding down that also for a few lines. The whole mass was covered with epithelial detritus and pus. The patient was anæsthetised, and the whole mass thoroughly scraped away with a curette. It was soft and bled freely; the raw surface was rubbed with a solution of chloride of zinc, sixty grains to the ounce of water; the middle ear was well disinfected and also the Eustachian tube, which was so patent that fluids flowed easily down it when the ear was syringed. Healing rapidly progressed, the raw surface being scarcely recognisable in two weeks' time.

Remarks.—Although the odour and appearance of the growth were so suggestive of gonorrhœal warts, yet no history of infection could be arrived at, and unfortunately no cultivations were made, hence the question arises whether the irritation causing the growth was an infective one or merely due to the acrid character of the discharge. The theory of infection is to a certain extent borne out by the fact that the growths on the tragus were obviously secondary to that on the concha, for whilst their surfaces were in contact their bases were free. Dr. Payne has shown[3] that simple warts in other parts are sometimes infective, so the infection was not necessarily from the gonococcus. To the free patency of the Eustachian tube is due the absence of symptoms from plugging of the meatus externus.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

A CASE OF COLLAPSE FROM VOMITING AND DIARRHŒA TREATED BY INTRAVENOUS INJECTION OF SALT SOLUTION.

(Under the care of Dr. STURGES.)

THIS case is a most important addition to those which have already been published as to the efficacy of the injection of saline solutions where excessive loss of blood, or of the watery constituents of the blood, has taken place. It will assist in bringing before the profession in a most convincing manner the value which the treatment has in some apparently hopeless cases. Dr. B. W. Richardson[1] has drawn the attention of the readers of THE LANCET to the effect produced by the injection of a saline solution into the veins of a woman who was moribund from cholera collapse. "She became quite conscious, sat up in bed, and signed a short will." The improvement was, however, only temporary, and required to be repeated, but each repetition was followed by the renewal of diarrhœa and cramps, and the patient died some hours later. Mr. Lane's[2] experience, which was also published in THE LANCET, was derived from a case of secondary hæmorrhage and collapse after an operation for cleft palate on a girl of thirteen. The results were almost miraculous, and the child rapidly recovered. He injected three pints and a half of common salt (one drachm to the pint) into the basilic vein. We have also recorded a case under the care of Mr. Anderson[3] of Nottingham, in which a fatal result from secondary hæmorrhage was apparently prevented by the intravenous injection of a solution of common salt, forty grains to the pint. Eighteen ounces of this were injected, and although at the time very collapsed, within two hours "he was able to sit up and ask for his tea." An injection of twelve ounces of similar fluid was required next day after an operation to secure a wound in the popliteal artery from which the hæmorrhage had come. This was again followed by satisfactory results, and the patient, a lad of sixteen, recovered. The injection of ten ounces of a solution of phosphate of soda, twenty grains to the ounce, was employed in a patient almost moribund from loss of blood due to wounds of the neck, with immediate benefit. Before the injection the pulse was quite imperceptible at the wrist, the pupils dilated and fixed, and the conjunctivæ insensitive. A case in which much benefit of a temporary character was obtained is also recorded in our columns. It was that of a man aged fifty-four, under the care of Dr. Churton, who from excessive vomiting due to cancer of the stomach became prostrate and pulseless. Here again the improvement was very marked whenever the injections were used. Dr. Churton's remarks on his case are interesting. We have referred to the experiments of Messrs. Dastre and Lange, who say that the expression "toxic dose" has no meaning so far as the salt solution is concerned. There is no such thing as a toxic dose, but there is a toxic rapidity. Their experiments are important, and will be found in detail in the *Archives de Physiologie*. For the notes of this case we are indebted to Mr. Horace Collier, house physician.

W. H——, aged nine months, was admitted to the Hospital for Sick Children, Great Ormond-street, on Oct. 26th, 1891. For four months he had been under care as an out-patient for congenital syphilis and rickets, with several attacks of diarrhœa. He was, upon admission, cold, pale, shrivelled-looking, completely quiet, and with sunken eyes and hollow-looking orbits. The history was that there had been severe diarrhœa and repeated vomiting for two days.

The child was at once rendered warm, and brandy

Digitized by Google

and meat-juice were administered in small quantities. Eight hours later the patient was still more collapsed, and appeared to be near death. He had vomited frequently since admission. The house physician exposed the left external jugular vein, where it was superficial to the sterno-mastoid, and slowly injected with a double-nozzled syringe twelve ounces of distilled water containing thirty-six grains of common salt and rather more than a drachm of brandy, the temperature of the solution being kept at 101°. The reaction appeared before the operation had been completed, the pulse becoming bounding, the face flushed, the skin hot, and the child very restless. The temperature was 104·8° three hours later; it remained at this level for two hours, and gradually and almost regularly fell, reaching 98 6° thirty-six hours from the time of the injection. The very marked restlessness was combated with opium. The child vomited once only after the operation. The diarrhœa was treated with grey powder and the compound ipecacuanha powder, and the patient showed no further complication and recovered.

Remarks by Mr. COLLIER.—The shrunken appearance and sunken eyes of such a patient show how wanting in fluid the tissues are; and if, as in this case, owing to the condition of the mucous membrane of the stomach and to the frequent vomiting, the absorption of fluids from the alimentary tract becomes greatly interfered with, it appears rational to make an intravenous injection. This case illustrates well the immense value of saline injections, the revival of the practice of which we owe to the late Dr. Wooldridge and to Mr. Arbuthnot Lane.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

TWO FATAL CASES OF LORETA'S OPERATION.

(Under the care of Mr. PAUL SWAIN.)

THE operation of digital divulsion of the pyloric orifice of the stomach has been performed many times since the account of the first operation by Loreta was published in THE LANCET.[1] These examples of this method of operating show that the procedure is attended with some considerable risk. The first patient died with a return of vomiting on the fifth day, the second from collapse four hours after the operation. An important thing in the second case is the condition of the pylorus as found at the necropsy. Loreta is reported to dilate the opening until his fingers are three inches apart. Here the stretching was very much less than that, and yet a complete rupture of the wall was found. Dr. Barton[2] gives a mortality after this operation of 40 per cent., whilst Dr. Ball[3] estimates it at 33·3 per cent. Dr. Weir,[4] in a clinical lecture, strongly recommends the performance of gastro-enterostomy in simple pyloric stenosis in preference to the operation for the relief of the condition recommended and practised by Loreta, giving a mortality of only 11 per cent. in such cases. The improved methods of performing it have certainly lessened the risk which formerly attended this operation. For the notes of these cases we are indebted to Mr. W. Gifford Nash, late house surgeon.

CASE 1.—Eliza T——, aged thirty, who has had three miscarriages but no children, was admitted under the care of Dr. Prance on March 17th, 1890. She stated that two years previously she first suffered from vomiting and pain after food, the pain not being relieved by vomiting. For three months she had been losing flesh, and for six weeks had suffered much from pain in the stomach and vomiting after food.

April 4th.—The patient has been sick two or three times daily since admission, the vomit consisting of curdled milk. The right kidney is mobile, and the abdominal aorta pulsates very forcibly. There is no abdominal tumour.

May 9th.—For a week has been passing dark, clotted blood in her motions.

16th.—There is some thickening of the structures overlying the abdominal aorta.

23rd.—Mr. Swain examined the abdomen under methylene, and in the left half of the epigastrium found a resisting mass apparently connected with the stomach. Splashing was obtained in the stomach.

June 1st.—The patient suffers much from headache and nausea.

27th.—She goes home to-day unrelieved. She has been treated by dieting and all kinds of drugs.

Aug. 5th.—She was readmitted under Mr. Swain for constant vomiting, coming on about half an hour after taking food. The vomit, which is never offensive or copious, neither contains sarcinæ nor blood. There is still some thickening in the left half of the epigastrium. She is losing flesh.

17th.—Under methylene, followed by A.C.E. mixture, an oblique incision was made parallel to and one inch below the left costal margin, commencing in the middle line. The stomach was found, and a two-inch incision was made in the greater curvature, commencing an inch and a half above the pylorus. The pylorus was thought to be thickened. Its orifice was searched for, and found after a long search; it was contracted down to the size of a goosequill. The muscular wall was not indurated and the mucous coat ulcerated. The little finger was first forced through and the opening further dilated so as to admit two fingers with ease. The stomach wound was closed with fifteen Czerny's and fourteen Lembert's sutures. The abdominal wound was then closed with silkworm gut. The patient was fed with peptonised nutrient enemata. She was frequently sick for the first three days after operation, the vomit consisting of grumous fluid. On the fourth day a teaspoonful of milk and soda-water was given every hour. On the fifth day vomiting returned, and the patient gradually sank from exhaustion.

Necropsy.—There was no peritonitis, and the stomach wound was firmly closed.

CASE 2.—Maria H——, aged thirty-seven, a single woman, was admitted under the care of Mr. Swain on June 23rd, 1891. She stated that ever since childhood she had been subject to pain in the stomach and vomiting of food, sometimes directly after a meal, and at others some hours later. At times she has gone for months without vomiting at all. She has lived on milk for a month at a time, and has improved under it. During the attacks of vomiting and pain she rapidly lost flesh and as rapidly improved when the vomiting ceased. She has never been so thin as now. At the age of fourteen she had an attack of ulceration of stomach which nearly proved fatal. For fifteen years or so she has vomited altered blood, and for one year noticed a stationary lump in the abdomen. The bowels acted regularly until two months ago, but since then have been constipated. On admission, the patient was a very pale, emaciated woman. On examining the abdomen there was an evident fulness below the level of the umbilicus, chiefly on the left side. The dilated stomach, or what appeared to be it, was situated in the hypogastric, umbilical, left lumbar, and iliac regions. The great curvature lay in the hypogastric, left lumbar, and iliac regions just above the pubes and Poupart's ligament. The pylorus lay just below the umbilicus, and the cardiac end just below the ninth costal cartilage. There was a tender mass just below the umbilicus fixed to the anterior wall of the pyloric end of the stomach. Splashing was easily obtained. The tympanitic stomach note was obtained over the area above mentioned, and above it appeared the transverse colon. There was a resonant note over the normal position of the stomach, but this was not so tympanitic as over the displaced stomach. The stomach was washed out daily with boracic solution. It easily received forty ounces of the solution. The mucus washed out was tinted brown, and contained torulæ and sarcinæ. The patient vomited about a third of a pint of brownish fluid two or three times daily. She suffered great pain, requiring frequent injections of morphia, and notwithstanding being fed by the mouth and rectum continued to lose flesh.

On July 4th, the stomach having previously been washed out, chloroform, followed by the A.C.E. mixture, was given, and an incision three inches long made in the left linea semilunaris, about midway between the umbilicus and pubes. What appeared to be the dilated stomach was at once exposed, nothing being seen of the great omentum. The lump proved to be a coil of small intestine, adherent to the front of the pyloric end of the stomach. The pylorus was felt to be thickened and constricted. The stomach was opened by an incision two inches and a half long in its anterior wall and the pylorus easily found, admitting the tip of the index finger with difficulty.

[1] THE LANCET, 1883, vol. ii.

[3] Medical Record, 1890. [4] Medical Bulletin, Phila. 1889.

Digitized by Google

First one finger, then two were introduced; next both index fingers, and drawn asunder to admit a third. A firm ring or band was felt, and heard to suddenly tear or give way. The wound in the stomach was sutured with a double row of Lembert's silk sutures, and the abdominal incision closed with silkworm gut. The patient was very collapsed, never rallied, and died four hours later, after having vomited a pint of brownish fluid.

Necropsy. — On opening the abdomen the distended stomach was at once seen, and lying in front of it near its pyloric end a coil of small intestine firmly adherent to it. On tracing up the lesser curvature of stomach was found a tube which was at first thought to be the œsophagus. On tracing this further upwards, to the left was found a second stomach, about the same size as the lower stomach, and situated in the usual position. On opening the two dilatations they were both lined with rugæ, and were undoubtedly both parts of the same stomach. The constricted portion, which formed a tube quite two inches long, was the seat of a large firm cicatrix. Near the pylorus was a cul-de-sac about the size of a hen's egg, evidently the seat of an old ulcer. The outer surface of this cul-de-sac was adherent to the coil of small intestine and to the first part of the duodenum. The pylorus was also the seat of a cicatrix. The constriction of the pylorus was partly due to this and partly to the dragging of the cul-de-sac from outside. At the bottom of the cul-de-sac was a slightly elevated ulcer about the size of a shilling. On opening the duodenum it was found to be very thin, and its junction with the pylorus at the back was quite torn through, so that blood and gas were extravasated into the subperitoneal tissue around the pylorus. The upper half of the hour-glass-shaped stomach was empty, but the lower contained dark-brown grumous fluid. The glands of the mesentery were much enlarged, especially those around the pylorus.

Remarks.—Case 1 was treated for ulceration of the stomach from March 17th to June 27th. The symptoms appeared to be increased by a neurosis, of which the pulsating aorta was evidence. When she was readmitted in August she was very weak and emaciated, and although there seemed to be very little chance of Loreta's operation succeeding, still it was felt to be right to give her the only chance. In Case 2 again the patient came under treatment in such a weak and emaciated condition that an attempt was made by rectal feeding to strengthen her for the operation. The hour-glass shaped stomach produced a very interesting and puzzling condition, which was not diagnosed until after death. It showed very well how such a condition is produced by the contraction caused by the cicatrisation of ulcers. Mr. Swain felt that both these cases were, from circumstances over which he had no control, operated on too late.

CUMBERLAND INFIRMARY, CARLISLE.

TWO SURGICAL CASES.

(Under the care of Dr. LEDIARD.)

IN connexion with the cases of conical stump published in THE LANCET of Oct. 3rd, under the care of Mr. Owen of St. Mary's Hospital, the following case may be of interest, as it resembles closely the third described by him, and also one which was under the care of Dr. C. A. Powers. We are indebted to Mr. James B. Bird, house surgeon, for notes of these cases.

CASE 1. *Conical Stump.*—G. M——, a schoolboy aged fourteen years, was admitted into the hospital on Sept. 23rd, 1891. He had the left upper arm crushed seven years ago, and it was amputated some distance above the elbow. A conical stump resulted some years later, and three years ago Dr. Lediard resected the humerus, leaving ample flaps. On admission the patient complained of the stump, which on examination proved to be conical, the bone protruding at the apex and causing pain. The skin was adherent to the bone. The bone protruded about half an inch. There was some pus.

Sept. 25th.—Over two inches of the humerus were removed to-day.

On Oct. 7th the stump had almost healed, and on the 14th the patient was discharged.

The above account shows how active the upper epiphysis of this humerus has been, and it bears out the fact that conical stump is very apt to result in the arm after amputation in boys. It is curious that the bone seems to have grown more rapidly during the last three years than it did during the seven years previously. Unfortunately, it is not known how much bone was removed in the first instance, in proportion to the length of the flaps.

CASE 2. *Necrosis of Sternum.*—A. W——, housewife, aged twenty-two years, was admitted on July 29th, 1891, complaining of discharging sores over the breast-bone. The disease had commenced four months ago, after her confinement, when a swelling was noticed over the middle of the sternum. This swelling burst, and had discharged pus up to admission. When the patient was admitted she was found to be a healthy-looking woman. There were three discharging sinuses in the mid-sternal region. Dead bone was felt when the sinuses were probed. On Aug. 7th the sternum was exposed by an incision through the soft parts, and after gouging for some time, two somewhat flattened sequestra were removed, one being over an inch in length, and the other about half an inch. The wound was plugged, and the case has since progressed favourably. The sequestra were lying loose in this case, one being about the middle of the sternum, and the other higher up. Mr. Erichsen, in his "Science and Art of Surgery," does not remark that these cases are rare, but one does not see them very often in practice.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Tubercular Ulceration of Tongue.—Sarcoma of Duodenum.—Pathological Conditions in the Breast associated with Carcinoma.

AN ordinary meeting of this Society was held on Jan. 5th, the President, Sir George M. Humphry, being in the chair.

Mr. CHARLES A. MORTON of Clifton showed a specimen of Tubercular Ulcer of the Tongue from a man aged fifty-five, under the care of Mr. Penny, in the Bristol General Hospital. The ulcer had almost healed, but was beginning to break down again when the man died of phthisis. The ulcer was at the tip of the tongue. Several minute ulcers formed and coalesced. There was less induration than in an epithelioma. Microscopic sections showed the tissue infiltrated with small, round, and giant cells containing numerous tubercle bacilli. The tubercular growth extended quite half an inch below the ulcer, showing the need of free removal in these cases if excision be performed, although the base was not indurated. The submaxillary glands were caseous. There was advanced pulmonary and laryngeal phthisis, also tubercle of an epididymis. The author did not think the phthisis could have been produced by the inspired air passing over moist tubercular discharge, but more likely by inoculation of an abrasion on the tongue from rough teeth by bacillary sputum; or that the ulceration on the back of the arytenoids had been caused by swallowing the discharge from the ulcer, and that the disease had then spread into the larynx and lungs.—Mr. MORTON likewise showed a specimen of Tuberculous Ulcer of the Tongue, excised by Mr. Munro Smith in the Bristol Royal Infirmary, which he had examined microscopically and found the same appearance as in the first case, except that instead of there being as many as a dozen bacilli in a single giant cell, he only found three in ten sections, each one in the centre of a giant cell. There were signs of phthisis at one apex. The submaxillary glands were slightly enlarged. This ulcer was also close to the tip, between it and the floor of the mouth; a smaller one existed by its side. The man was aged thirty-four, and the ulcer was of six months' duration.—Dr. PENROSE remembered seeing a case in a child, in which he demonstrated the presence of tubercle bacilli. There was no local condition, such as rough teeth, to account for the presence of the lesion. It was situated at the back of the tongue, close to the epiglottis, and both larynx and lungs were found to be tubercular.—Dr. HADDEN recalled a case which he had described in the Society's Transactions in 1883. Later Mr. Barker had been through the literature of the subject, but he had failed to find a case in a child. Since then the speaker had seen many instances of tuber-

Digitized by Google

ocular lingual ulceration, in some of which that affection appeared to be the initial tubercular lesion. Often a local predisposing condition was observed to be present.—Mr. SHATTOCK referred to Mr. Butlin's suggestion of scraping these ulcers for purposes of diagnosis, and he asked the author if he thought that this proceeding would have aided in elucidating the cases under discussion.—The PRESIDENT thought that the rarity with which the tongue was attacked by tubercle depended on the thickness of its epithelial covering, which was greater over this organ than at any other part of the digestive tract.—Mr. MORTON, in reply, said that the site of infection was probably usually an abrasion, the anterior part of the tongue being frequently nipped between the teeth or damaged by traumatism, as, for instance, in one case a man was attacked by tubercular ulceration of the tongue who was in the habit of carrying tin tacks in his mouth. He thought that scraping should prove of value in aiding diagnosis.

Dr. ROLLESTON showed a specimen of Duodenum, in which the mucous membrane of the first, second, and commencement of the third part was greatly altered; the surface was raised and rough, from the presence of plaques of material resembling hardened Peyerian patches. This growth was ulcerated, and, in the region of the biliary papilla, and again at the commencement of the third part, there was considerable destruction of tissue. In the latter situation there was a cavernous ulcer passing under the pancreas; its walls, rough and irregular, were formed of muscular coats infiltrated with growth. On the floor of the ulcer the inferior pancreatico-duodenal artery was exposed and eroded. The pancreas was not infiltrated with growth, but was expanded over infiltrated and enlarged glands at its head. The mesenteric glands, and those in the portal fissure, were enlarged and infiltrated with growth, but there were no enlarged glands elsewhere, and no growths in the liver, spleen, or rest of the intestine. The stomach and small intestine contained a large quantity of recently extravasated blood. Microscopically the submucous coat was seen to be the part primarily affected with a growth composed of small and medium sized round cells; their nuclei were relatively large to the scanty surrounding cell substance. Between the cells delicate fibrillæ and coarser strands of fibrous tissue, probably derived in part from the tissues invaded by the growth, could be made out. The growth infiltrated the muscular coats and passed up to the mucous coat. The latter had disappeared from the greater part of the duodenum, and its place was taken by growth with some blood channels devoid of proper walls. The growth had some of the characters of a lympho-sarcoma, but was limited to the duodenum and its adjacent glands. Dr. N. Moore, in the thirty-fourth volume of the Society's Transactions, had described a case of lympho-sarcoma limited to the duodenum. The specimen was taken from a patient thirty years of age, who had died in St. George's Hospital under Dr. Whipham of hæmatemesis.

Mr. RAYMOND JOHNSON read a paper on Pathological Conditions of the Mamma associated with Carcinoma. His investigations had been undertaken with the object of ascertaining whether pathological evidence could be obtained indicating the propriety of the complete removal of the whole organ in cases of carcinoma. The condition of the breast tissue had been carefully ascertained by naked-eye examination and the use of microscopic sections. From a practical point of view, it was very convenient to divide carcinoma of the breast into two varieties, the nodular and the infiltrating. The infiltration of the gland might arise through the lymphatic, and also probably by a widespread carcinomatous change affecting the glandular tissue. Specimens and drawings were shown exhibiting both these processes. In a case of infiltrating carcinoma in a woman aged twenty-six years, microscopic examination of parts of the breast appearing normal to the naked eye revealed masses of cancer cells apparently lying in lymphatic spaces. On the other hand, in another specimen of the infiltrating variety the microscopic appearances strongly suggested that a widespread carcinomatous change was involving the whole organ—sections showing the new growth arranging itself around the small ducts, which were themselves apparently normal. In this paper, however, attention was especially directed to the nodular form of the disease. In the case of a woman aged thirty-four years a small nodular carcinoma was situated at the axillary border of the left breast. After removal, two small nodules were found at the sternal end of the breast, each having the typical structure of glandular carcinoma, whilst microscopic examination of the central part of the gland showed marked changes in the epithelium, to be described later. Reference was then made to the nodules described by Heidenhain in the fascia over the pectoral muscle, and a drawing was shown of such a nodule invading the muscle at a distance from the tumour itself. Small cysts in the breast tissue were not uncommon, but no evidence was obtained to show that their relation was more than accidental, cysts being common at the age at which cancer is common. Possibly, however, such cysts might arise as the result of the blocking of the ducts by the growth of the tumour. With the microscope changes were often found when the naked eye gave no evidence of disease. Thus in one case the microscope showed invasion of remote parts of the breast through the lymphatic spaces as in the infiltrating variety of the disease. More common, however, were proliferative changes in the epithelium of the acini. The latter were somewhat dilated, and more or less blocked by masses of swollen, faintly staining cells, often with indistinct outlines. These changes were well seen in a small indurated area excised by Mr. Godlee from the centre of the breast of a woman aged forty years. The condition was probably of the nature of a chronic inflammation, and there were no signs of tumour formation. Specimens were also shown exhibiting these changes in breasts the seat of carcinoma, as well as in the breast of a lady whose opposite breast had been excised by Mr. Berkeley Hill for carcinoma several years previously. It was suggested that these proliferative epithelial changes probably stood in the same relation to cancer of the breast as chronic superficial glossitis did to cancer of the tongue—viz., it represented a possible precancerous condition. The conditions found in the breast in association with carcinoma were summarised as follows:—(*a*) Gland tissue to all appearances healthy; (*b*) gland tissue atrophied, with large admixture of fat and fibrous tissue; (*c*) chronic proliferative epithelial changes; (*d*) infection of the gland through the lymphatics; (*e*) cystic changes; and (*f*) presence of simple tumour. The conclusion to be drawn from these observations seemed to be that as far as possible all the gland tissue should be removed in excising a cancer of the breast. Breast tissue was liable to be left in reflecting skin flaps from the surface of the gland, at the periphery of the breast, and on the surface of the pectoral muscle. As far as possible all overlying skin should be removed, and the surface of the pectoral muscle should be cleaned, with possibly removal of the superficial fibres. Finally, specimens were exhibited showing fragments of breast tissue left behind in the usual operation of excision, and others showing that such fragments might in some cases at least be the starting-point of recurrent growths. Mr. Johnson expressed his thanks to the staff of University College Hospital for the free use of their cases, and especially to Mr. Marcus Beck, at whose suggestion he had undertaken the observations.

Mr. CECIL F. BEADLES read a paper on some Histological Changes in the Breast found in association with Glandular Carcinoma. He commenced by saying that the condition of the breast tissue apart from the actual carcinomatous tumour appeared to have been little, if at all, investigated. After a careful search into the literature of the subject, he had only found allusions to the subject by Cornil and by Creighton. As a result of microscopical examination of about a hundred breasts amputated for carcinoma, he was able to state that these breasts were never in what might be considered as a normal state, but it was doubtful to what extent the conditions found were dependent on the presence of cancer. He then referred to the frequency with which small carcinomatous nodules might be found at a distance from the larger growth, and having no connexion with it. He then described the changes found in the stroma of the breast lobules, and said there could be seen in different cases all the stages usually described as being present in chronic interstitial mastitis—namely, a small round-celled infiltration, a stroma formed of connective tissue cells, and of dense fibrous tissue, associated with atrophy of the gland acini, or with the formation of cysts. There was often also a marked proliferation of the epithelium within the acini, and when this was considerable the central cells were usually degenerated. A peculiar change found in some gland acini of the breasts affected by malignant disease was then de-

Digitized by Google

scribed. This consisted in the increase, combined with great irregularity in size of the epithelial cells, some being very large and in character indistinguishable from malignant cells. These were often associated with degeneration of the others, the débris formed by cells and cell secretion being often of a yellowish-brown colour. This condition he looked upon as a stage between simple œdema and glandular carcinoma, which was, in fact, commencing malignant disease. A papilliform change, sometimes found in the epithelium of the ducts, was next described. This presented itself in two forms—in the one, groups of spaces were lined by large columnar epithelial cells, and into these spaces small processes passed from the stroma. This condition he had found in breasts that contained no form of malignant growth. In the other form there was a fine branching intracystic growth of fibro-cellular tissue covered by smaller columnar cells. The process of degeneration could be traced in adjoining spaces, both of the stroma and epithelium. In conclusion, Mr. Beadles believed the changes that he had described in the gland acini were independent of the primary growth, and were probably produced by the same cause as the latter; and he stated that in his experience the direct infection of the breast through the lymphatics was extremely rare, except in the immediate neighbourhood of the growth. These changes in the epithelium might account for recurrences of the disease in some cases, so that very great care should be exercised in the removal of all traces of the mammary gland.—The PRESIDENT said that this was an illustration of the close relation which pathology had to practice. Clinically, though it was not surprising to find cancer localised to one spot, yet its return in a distant part was common. This fact suggested that in many cases disease might be lurking in a distant part of the gland, though it was not to be detected by any ordinary method of examination. He had often noticed that after the removal of a breast for cancer there would happen a recurrence in the neighbourhood in tissue which was not apparently mammary. This, he thought, happened too frequently to be accounted for by the idea that in every case portions of breast tissue had been left behind. He believed these local growths were situated in the connective tissue or in the skin. Mr. Stiles of Edinburgh had been working very carefully at the nature of the tissue which was to be found on the axillary side of the breast, between it and the axillary glands, and he had found that much of the connective tissue of this region possessed a glandular structure which might of itself be the site of recurrence. The results of amputation of the breast had been more successful of late years because of the freer removal of the tissues. The skin was now often much more freely taken away than formerly, the gap left being filled up by cuticle shaved off after the method of Thiersch. He held that this free removal of skin was a very important matter in these operations. He agreed that mammary cysts had no particular relation to cancer. He remarked that the mammary glands were very peculiar organs: they might remain functionless through life, they might be repeatedly and actively functional for limited periods, or one organ might remain entirely functionless while the other was active, and he thought it would be a matter worth inquiry as to which of these three conditions was the most frequent predecessor of cancer. He referred in conclusion to Dr. Creighton's paper on the conditions of the cells of the mammary gland under circumstances of evolution and of involution and their bearings on cancer.—Mr. BOWLBY thought that many of the changes which had been described had nothing to do with cancer. He had examined many breasts taken from persons of middle age not affected with cancerous disease, and he had found similar changes in these also. They all showed involution changes in the ducts, acini, and surrounding tissues. There was proliferation of the epithelium in the acini and ducts; collections of cast-off cells in the acini and small celled growth round both ducts and acini, with formation of fibrous tissue interstitially. These changes would only at the most predispose breasts to affection with cancerous disease. It should be remembered that a cancer growth often spread a considerable distance beyond its apparent limits, and the breast tissue in these subjects was usually so little in depth that a small cancer nodule would lie in relation with both the skin above and the pectoral fascia below. He asked the authors how far from the cancer nodules were these changes found? These papers seemed to suggest that secondary growth, and at a part of the gland distant from the primary focus, was almost sure to follow; but he did not think that this result was nearly so common as had been thought. At St. Bartholomew's Hospital it was the practice of some, if the growth were limited to the axillary border of the gland, to remove the growth only and leave the gland; where this had been done, if recurrence followed, it was usually not in the breast at all, but in the axillary glands. If the tumour lay nearer the sternal side of the breast the remainder of the breast tissue was more likely to be affected, because the lymph stream was directed towards the axilla and traversed the mammary region to arrive there.—Mr. WATSON CHEYNE said that he had examined the specimens prepared by Mr. Stiles and agreed with his conclusions. He felt convinced that cancer spread by growth along the course of the lymphatics rather than by continuous growth along the ducts. The lymphatic plexuses in the mamma were so free that he did not feel justified in adopting partial amputation, even if the growth appeared to be limited to the axillary border. It was of importance always to remove the pectoral fascia, for lobules of the gland penetrated it and lymphatic vessels traversed it. He had examined a large number of small nodules of recurrent growth, and in the great majority of cases they were imbedded in a bit of breast tissue which possessed healthy acini; this again pointed to lymphatic infection.—Mr. JOHNSON in reply said that he was at present engaged in examining a number of specimens of breasts of women between forty and forty-five, and, though he had found changes, these were not nearly so marked as those in several of the carcinoma cases. Where he had referred to tissue examined from a part of the gland remote from growth, it meant that the specimen was taken from the opposite hemisphere of the gland at a distance of two or three inches from the primary growth. He had found the changes which he described in many of the cases he had examined, but not in all.—Mr. BEADLES likewise briefly replied.

The following card specimens were shown:—

Dr. R. G. HEBB: Microscopical Sections of Tubercular Endocarditis.

Dr. H. D. ROLLESTON: Depression of Frontal Bone of an Infant aged nine months.

CAMBRIDGE MEDICAL SOCIETY.

FRIDAY, JULY 10TH, 1891.

Mr. J. H. HEMMING, President, in the chair.

Recurrent Growth of Cornea.—Mr. WHERRY showed a patient with a firm, pale, sessile growth of the cornea and conjunctiva, not quite extending to the edge of the pupil, but interfering a good deal with vision from its projection and altered vascularity. This growth had recurred after removal two years and a quarter ago. A drawing made before the operation showed it more lobulated or papillated in shape. There had been entire immunity during two years. Another operation was proposed and a transplantation of mucous membrane of the lip into the gap. The growth was probably sarcoma. This patient had large flat warts on the back of the left hand of four years' growth, not now spreading; each papilla ended in a fine bristle or hair, not many hairs between the papillæ.

Cases of Deafness treated by Injection of Pilocarpin.—Mr. T. HYDE HILLS read the notes of two cases of deafness treated by the injection of pilocarpin. One was a man aged sixty-five, deaf in both ears, and the other was a lady aged thirty-one, also deaf in both ears. Both cases ran much the same course, the initial injection commencing at $\frac{1}{10}$ gr., and being increased in a few days to the maximum of $\frac{1}{4}$ to $\frac{1}{3}$ gr. Salivation was produced with $\frac{1}{3}$ gr. The treatment was prolonged for about seven weeks in each case, daily, with occasional intervals of one or two days. In the first place (i.e., of the man of sixty-five) the watch was heard before treatment on the right side 3 in., and on the left side 12 in. At the end of treatment the patient heard at a distance of 18 in. on the right and 6 ft. on the left side. In the second case the patient heard the watch on the right side at $1\frac{1}{2}$ in., and on the left at $\frac{1}{2}$ in. At the finish he could hear on the right side 9 in., on the left $3\frac{1}{2}$ in. At the commencement the patient heard a tuning-fork on the mastoid: right 13 in., left 12 in. Both cases gradually deteriorated, and three weeks after treatment were as deaf as before treatment. Another case

Digitized by Google

which was treated by Mr. Field about the same time, and which Mr. Hyde Hills had opportunity of seeing from time to time, improved for the time, but had exactly the same result. Pilocarpin is said to influence labyrinthine deafness. But certainly middle-ear deafness is also improved. It is difficult to see how pilocarpin can influence cases of so-called labyrinthine deafness. The physiology of the labyrinth is so hopelessly complex and so little known that its (pilocarpin) action there cannot with any degree of certainty be explained. It may be that there may be some change caused in the constituency and specific gravity of the perilymph or the endolymph, which may put things right and allow of effective conduction of vibrations. Or it may be that the fibres of the basilar membrane, or some part of the infinitely delicate membrane of Corti which hitherto has been damped by the accumulation of concentrated secretion, may be set free to respond again to normal stimuli. But of this we have no proof. On it we might theorise *ad infinitum*. But, on the other hand, it seems easy to see how a copious secretion from the aginparous and muciparous glands of the Eustachian tubes could so flush those canals that their walls should no longer adhere, and atmospheric pressure on each side of the tympanic membrane should thus be rendered again equal, and the oscillations of that membrane and the ossicles, and therefore the fluid of the labyrinth, should again be adequate to stimulate the sensitive nerve endings. Or again—and this seems to me most probable—it may be the delicate joints between the ossicles that are influenced. It is easy to see how the joints can be interfered with by deposit, rheumatic or otherwise, and the pilocarpine may so influence them as to set them free to act more efficiently. Iodide, however, seems not to have any such effect.

PLYMOUTH MEDICAL SOCIETY.

SATURDAY, NOV. 14TH, 1891.

Mr. W. D. STAMP (Plympton), President, in the chair.

Exhibition of Cases.—Mr. WOOLLCOMBE showed a man aged fifty-two who nine months before had been successfully injected with pyoktanin for a malignant growth of the right ilium. He now presented an ankylosed hip-joint, but no signs of recurrence of growth.—Mr. LUCY showed a man aged twenty-one with a firmly ankylosed right elbow-joint (the seat of former tubercular arthritis), which nine months ago was riddled with sinuses. Thirty-five injections of Koch's tuberculin were given; the sinuses all healed, and have remained sound after the lapse of six months.—Mr. WOOLLCOMBE showed a boy aged three on whom two months previously he had performed Macewen's radical cure for a Right Congenital Inguinal Hernia. A firm cicatrix was now present, and the invaginated sac could be distinctly felt as a disc closing the internal abdominal ring.—Dr. CHEYNE WILSON exhibited specimens of five new drugs.

Influenza.—Dr. C. R. PRANCE opened a discussion on influenza. After reviewing the various names given this peculiar epidemic, he approved of the German term "epidemic catarrhal fever." He cited the large amount of literature on the subject, dating back to the twelfth century, the contradictory evidence as to influence of season, weather, &c., considering that Europe and the Antipodes were visited at one and the same time, but the general spread of invasion had always been from east to west. The stay of the epidemic in any locality seemed to be a month or six weeks, and adults were attacked more often than children, the strong as well as the delicate, being no respecter of persons or classes. Dr. Prance stated that catarrhal symptoms were more marked in the epidemic of 1847 than in last winter's, but he could offer no theory as to the *materies morbi*. Reference was made to the long-enduring and varied sequelæ, mostly of a nervous character, to the absence of proof of its contagious nature but strong proof of its infectiousness, modified generally though by atmospheric conditions. The differential diagnosis between typhoid fever and influenza was touched on, and in conclusion the lecturer said early recognition and prompt treatment were called for imperatively.—Mr. ELLIOT SQUARE dwelt on the difficulty of diagnosis in the early stage of the disease, and inquired of Dr. Aldridge the frequency of post-influenzal insanity.—Dr. MEENES remarked that Dr. Huxham of Plymouth had written a most graphic account of the disease in 1733.—Fleet-Surgeon ELLIS, R.N., cited the case of influenza breaking out on H.M.S. *Orion* in 1890 as proof of the infectiousness of the disease, they having received off Sumatra several men of the troopship *Himalaya*, on board which influenza was then raging.—Dr. L. FOX said that in China if a traveller calling for a night's lodging had a cough he was told to go elsewhere, proving that the Chinese recognised the infectiousness of influenza. He also cited the outbreak of influenza on board three ships in Brest Harbour in 1890, consequent on the receipt by an officer of a parcel from Paris, where the epidemic then raged.—Surgeon-Captain MYLES, M.S., considered dengue very similar to influenza. The number of engineers who went on the sick list was small compared with the line privates, the pay of the former only being stopped in case of sickness.—Dr. ALDRIDGE (Plympton) remarked that in lunatic asylums the staff more frequently than the patients contracted the disease. He had never found a single case of insanity traceable to influenza admitted into his asylum.—Mr. LEAH found that old and bedridden people were not subject to influenza. An attack was often followed by a second nine months or a year afterwards.—Dr. WILLOUGHBY said that at St. Bartholomew's Hospital during the last epidemic he found that the inmates of beds adjacent to a case admitted with influenza almost always contracted the malady.—Mr. WOOLLCOMBE said that bearing on the question of infectiousness in four of the principal railway companies in England 5 per cent. of the drivers and stokers were attacked, while of the clerks who worked together in the same office 10 per cent. were affected.—Mr. LUCY asked Dr. Prance what he considered the incubation period of the disease.—Dr. PRANCE, in reply, said it was impossible to recognise any definite incubation period, as the onset was so sudden and unexpected.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

WEDNESDAY, NOV. 18TH, 1891.

Mr. A. R. ANDERSON, F.R.C.S., President, in the chair.

Acromegaly.—Mr. LOVEGROVE showed a case of supposed acromegaly in a man aged seventy-three, whose hands and feet exhibited much enlargement and thickening. There was no history of gout or rheumatism, and the thickening was general in all parts of the four extremities.—Dr. HANDFORD exhibited a case of tabes dorsalis with temporary arrest of the disease in a woman of forty-six.

Thrombosis of the Portal and Mesenteric Veins and of the Vena Cava.—Dr. HANDFORD described and showed the specimens from this case, which occurred in a man aged forty-one. He had suffered from deep jaundice for about twelve weeks, when he was suddenly seized with intense abdominal pain, œdema of the lower extremities, hæmatemesis, and frequent bloody stools. The patient rapidly became collapsed, and died within twenty-four hours. The cause of the long-standing jaundice was found to be a carcinoma of the head of the pancreas, which had led to a retention cyst containing about two ounces of clear fluid. The portal veins within the liver were filled with pus. The portion of the portal vein outside the liver was filled with an adherent, firm, partially decolorised thrombus. The mesenteric veins were hard to the touch and firmly plugged with a thrombus which appeared slightly more recent. The vena cava close to the liver was also blocked by a thrombus some days old. The intestines, large and small, contained numerous recent black coagula, which in many instances formed complete casts of the bowel. There were also numerous interstitial hæmorrhages into the coats of the stomach and intestines. Four very similar cases are recorded, in the Transactions of the Pathological Society, by Drs. Fagge, S. West, F. Taylor, and Goodhart in vols. xxvii., xxix., xxxii., and xl.

CREMATION IN FRANCE.—From a report drawn up on the subject of cremation in France recently it appears that, although strictly forbidden by the Roman Catholic priests, the total number cremated during the year 1891 was about 150. In 1889 the number was only 49.

Reviews and Notices of Books.

Lehrbuch der Organischen Chemie für Mediciner. Von Dr. THEODOR WEYL. Mit 11 Holzschnitten. Berlin: August Hirschwald. 1891.

WHEN the hope is expressed that a German work may be speedily translated into our own tongue, the author receives the best compliment an English reviewer can pay him. Dr. Theodor Weyl's manual is an admirable one, and contains not only all that is essential for students of medicine to know, but also information of value to the practitioner, and of service to the chemical teacher. We shall hail with satisfaction the appearance of a translation of this work, that it may be better available for the use of English readers. Works on organic chemistry commonly and properly start with a definition of this branch of the science; and accordingly we read that organic chemistry is the chemistry of the carbon compounds, and not that which deals exclusively with plant and animal products, which were the result, as it was hitherto supposed, of the action of so-called vital force. The plan of the work before us reminds us of the excellent little manual which was edited by the late Henry Watts, and well known as Fownes "Organic Chemistry." Like this work, it is divided into two parts — general and special. The general part—subdivided into nine lettered paragraphs—deals with the usual introductory matter, such, for example, as the qualitative and quantitative analysis of organic bodies, the deduction of formulæ from the percentage composition, the determination of vapour density, Raoult's method for determining molecular weight, structural formulæ, nomenclature, reactions and the physical properties, including the melting and boiling points of organic bodies. The special part is subdivided into two sections, Section I. being devoted to the methane derivatives or fatty group, and Section II. to the benzene derivatives or aromatic group. The chapters of Section I. are distinguished by letters, and the chapters of Section II. by figures. Here we may note that Chapter 1, according to the table of contents, treats of acids (Säuren) on page 139. On reference to this page, however, the letter K is found. For I, therefore, should be read K, for K should be read L, and so on through the section, I having by an oversight been omitted. We would draw the author's attention also to the wrong position assigned to many of the multiple numbers attached to the symbols. Thus hydrogen, when acting as a reducing agent on certain organic substances, is represented by H_6 instead of 6H; and again, O_3 is represented instead of 3O. This would represent the action of ozone rather than that of oxygen. The officinal preparations of the German pharmacopœia are strikingly underlined, so that they are made to stand out boldly from the rest of the matter.

Allusion may now be briefly made to some of the more interesting subjects which Dr. Weyl has aptly discussed. The composition of wine, beer, and spirits is entered into pretty fully in the chapter on alcohols, a complete analysis of many kinds being cited. Sulphonal is described under the heading "Sulphonic Acids," and the method of preparation is given, with the equations representing the reactions. In the account of chloroform we do not find any mention of the chlorination of ketones, by which chloroform may be produced. The chapter on fats contains an excellent, though brief, account of medicated soaps, transparent toilet soaps, and their adulteration, emplastra, and unguenta. This naturally leads to a description of the vegetable and animal fats, and the fats used as vehicles in medicine, of which lanoline is a type. The constitution of lecithin, a brain constituent, also finds a place in this chapter. The section on sugars includes an account of Emil Fischer's famous researches on the synthesis of glucose. Official sugar preparations like ferrum oxidatum saccharatum, ferrum carbonicum saccharatum, as well as troschisci and oxymel scillæ, are all referred to in this interesting chapter. Under the starch group mention is made of the use of starch and gelatine in capsules. Antifebrin is described together with the substituted anilines; it is obtained by acting on aniline with acetyl-chloride, when antifebrin or acetanilide and hydrochloric acid are obtained. Phenacetin is included with amido-phenols, being produced from amido-phenol by treatment with acetic acid. It is accordingly known to chemists as p-acetyl-amido-phenetol. Details of the process by which the curious substance saccharin is obtained are given in the section on sulphobenzene acids. Passing on, we come to the pyridin group, under which are very properly discussed the alkaloids, piperidin, piperin, conine, tropine, nicotine, and cocaine. They are, in fact, hydrogen additive products of pyridin C_5H_5N. The synthetic production of inactive conine by the reduction of allyl pyridin is of especial interest in this section. Then follows a section devoted entirely to the alkaloids, an account of the cocaine alkaloids being assigned two pages. This concludes with a short list of the ptomaines, putrescin, muscarin, neurin, &c., and their formulæ. Cholesterin follows closely on the camphors and terpenes; while the essential oils and resins are dismissed in the four concluding pages of the chapter. Under the title of "Animal and Vegetable Substances of Unknown Constitution," cantharidin, bilirubin, urobilin, biliary acids, and protagon are described. The latter, as is known, is assigned the formula $C_{160}H_{308}N_5PO_{35}$. Protein bodies are next discussed, and these of course lead to peptones, ferments, enzymes, and albumen. Finally, comes a terse, though instructive chapter on proteids, divided into glyko-proteids and chromo-proteids. Under the former are included mucin and mucoid, and under the latter hæmoglobin and its interesting compounds. The cumbersome formula $C_{636}H_{1032}N_{164}FeS_3O_{181}$ is stated to represent the hæmoglobin of the dog.

Dr. Weyl has obviously dealt ably and in a succinct fashion with a great number of valuable facts, and the pains which he has taken to give a fitting place to a full account of the remedies with which chemistry has lately furnished us will be appreciated by all those who believe that chemistry is not the least of the servants that faithfully minister to the wants of the healing art.

OUR LIBRARY TABLE.

A Handbook of the Diseases of the Eye and their Treatment. By HENRY R. SWANZY, A.M., M.B., F.R.C.S.I., Surgeon to the National Eye and Ear Infirmary, Dublin. Third Edition. London.—We are glad to find that a third edition of Dr. Swanzy's able treatise has been called for in the short space of six months from the issue of the second edition. Well printed, well illustrated, and of moderate compass, it affords just the amount of information that a practitioner who wishes to refresh his memory, or a student who is attending a course of lectures and is dressing in the ophthalmic wards of a hospital, requires. The present edition is larger by about fifty pages than the preceding one, and a few additional woodcuts have been added, raising the number from 148 to 158. In regard to the text it was not to be expected that the author would find any great novelties either in the way of pathology or of therapeutics, considering the shortness of the period that has elapsed since the publication of the last edition. He has, however, made various minor additions, omissions, and corrections, bringing the book up to date. Thus, for example, under the head of "Optic Nerve," he adds

Digitized by Google

that some, as Ulrick, maintain that in optic neuritis œdema, but not inflammation, of the optic trunk is conducted from the brain. He also mentions that hyaline or colloid outgrowths from the optic papilla are occasionally met with, presenting the appearance of bluish-grey mulberry-shaped nodules. Such growths originate in the lamina vitrea of the choroid at the margin of the papilla. They rarely cause serious blindness, and seem to be due to traumatisms. The sections devoted to glaucoma, to amblyopia and amaurosis, to affections of the orbital muscles, and to cataract are all remarkably well written. Dr. Swanzy still appears to favour that method of operating in which an iridectomy constitutes an essential feature, chiefly on the ground of the frequency with which prolapse of the iris follows, or is said to follow, the operation. Surely this is an error. Prolapse is not common if care be taken to make the incision just within the periphery of the cornea, to adapt the edges carefully, to instil a drop of eserine, and finally to avoid bandaging the eyes too tightly. As for the occurrence of irido-cyclitis in eyes from which the lens has been removed without iridectomy, it may, we think, be dismissed as an imaginary danger, or at least not more likely to follow the operation without than with iridectomy. Though differing from him in some details, we can recommend Dr. Swanzy's book as one of the most intelligently written and reliable text-books on diseases of the eye that, amongst the many which have appeared during the last few years, has as yet been written.

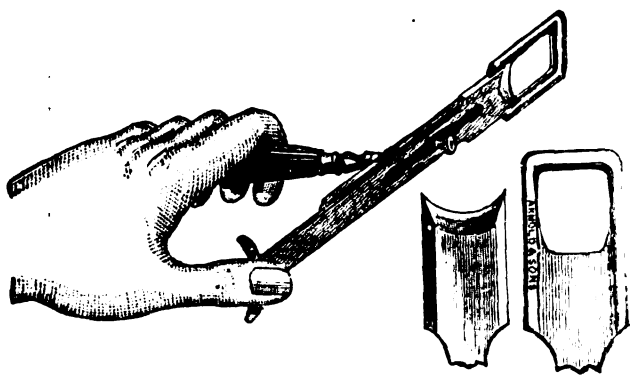
Archives of Pediatrics. A Monthly Journal devoted to the Diseases of Infants and Children. Edited by WILLIAM PERRY WATSON, A.M., M.D. Philadelphia: J. B. Lippincott Company. Vol. VIII., No. 95, November, 1891. — This number contains the minutes of the third annual meeting of the American Pediatric Society, held in Washington Sept. 22nd to 25th, 1891, and a portion of the transactions, which includes the address by the President, Dr. Rotch, on "Iconoclasm and Original Thought in the Study of Pediatrics," in which he says: "It is no exaggeration to state that a large number of sick infants and young children throughout the land are suffering from the vigorous treatment of their zealous medical attendants rather than from the disease with which they started"; as well as three papers, which do not contain anything new, by Dr. Latimer, Dr. Forcheimar, and Dr. Osler, on the "Diagnosis of Pneumonia in Infancy and Early Childhood." Dr. Dorland continues his original communication on "Affections of the Respiratory System in Infancy and Childhood, compiled and arranged in Tabular Form," and there is a good current literature on Hygiene and Therapeutics, Medicine, and Surgery, in their relation to Diseases of Children.

Brain: a Journal of Neurology. Parts LIV. and LV. London: Macmillan and Co. 1891.—This double number of the representative journal of neurological science contains several articles of interest and importance, which demand close study. The most prominent is a lengthy exposition from the physiological standpoint of the Sense of Effort, by Dr. Augustus D. Waller. It is largely based on experimental observation, and is also critical of the views of others. It should take an important place amongst contributions to cerebral physiology. Professor Chauveau writes on the Sensori-motor Nerve Circuit of Muscles, a topic cognate to that discussed by Dr. Waller. Dr. Morton Prince of Boston (U.S.A.) takes what may be summarily described as the psychological view of the inter-relations between mind and brain, in an article suggested by Dr. Hughlings Jackson's writings. But apart from these subjects of the "higher neurology," the journal abounds in excellent clinical and pathological records. Dr. Savill makes a contribution to the subject of sensory cerebral centres in his record, and comments on a case of anæsthesia and trophic changes consequent on a lesion limited to the gyrus fornicatus and part of the marginal convolution. Other clinical cases are contributed by Drs. Allen Starr and McBurney of New York, Dr. Bristowe, Dr. Handford, and Dr. Donkin. A "critical digest" of the subject of neurasthenia is contributed by Dr. Paul Blocq, of the Salpêtrière; and the number is also very rich in abstracts of neurological writings in other journals.

The two numbers of the *Bacteriological World*, September and October, give evidence that our American brothers are fully alive to the fact that it is necessary to diffuse a knowledge of bacteriology as widely as possible. Original articles, abstracts, or selections, lessons in bacteriology, reviews and notices, make up in each case a most interesting number. In the October number, in a contribution entitled "Notes on the Bacteriological Study of Diphtheria," by Wyatt Johnson, M.D., Montreal, the author has collected the results of a considerable number of experiments, from which he calculates that in 342 cases of diphtheria examined the Klebs-Loeffler bacillus has been proved to be present in no fewer than 327; in fifteen only was it impossible to find this organism. An extract from the Michigan State Board of Health on the Prevention of Small-pox is of interest, as showing what is being done in connexion with vaccination in the States.

Diaries &c. for 1892.—Messrs. Charles Letts and Co. (3, Royal Exchange) have forwarded to us an assortment of diaries of great variety and excellent in style; whilst the price brings them within the reach of everyone. The information which they supply is judiciously selected and of the most interesting kind. The "Improved Office Diary and Note-book for 1892" is a handsome book, devotes a page to each day, and is provided with a handy index. It can be obtained either of octavo or foolscap size. The popular "Desk Diary" contains a week's entries on every opening, and is interleaved with blotting-paper of good quality. The "Improved Pocket Diary" is another which can be recommended for notes, and which may be used as a cash-book. Perhaps the "A B C Medical Diary and Visiting List," with which is combined the prescriber's index of remedies and posological table, prepared for ready reference by medical men, will have special interest for our readers. It has for long been a favourite on account of its completeness and compactness, and it still continues to supply an excellent portable and compendious means of recording professional engagements.—We have also received from Mr. J. M. Richards, 46, Holborn Viaduct, what is termed a "Daily Reminder." It is suitable for the desk or pocket, and affords space for addresses and for daily entries.—Rudall, Carte, and Co., 23, Berners-street, W., publish "The Professional Pocket-book, or Daily and Hourly Engagement Diary for 1892," specially adapted for professional engagements, and constructed according to the plan of Sir Julius Benedict.—Another most excellent medical diary, that published by Smith and Co., and well known to the profession as "Smith's Diary and Visiting List," has given great satisfaction to those by whom it has been used. Within its pages will be found ample space for all the notes and memoranda which a medical man may have occasion to make on account of his professional services. The binding is strong and handsome.

Sell's World's Press and Advertiser's Reference Book, 1892. 167 and 168, Fleet-street, London.—Sell's Dictionary of the World's Press and Advertiser's Reference Book comes as a boon to others than "the great army of newspaper men," and undoubtedly is deserving of a very high place as a work of reference. The lists in the directory portion of the dictionary have been carefully revised and corrected



Digitized by Google

to date, and special indexes have been added to facilitate more rapid reference. This volume also contains articles of interest on press subjects by such well-known pressmen as Mr. James Walker, Mr. Stead, and Mr. Fox-Bourne. Mr. Walker supplies an able article on "The Growth of the Provincial Press in London," in the course of which he says: "I am well within the mark in saying that the editors, sub-editors, and reporters of provincial papers working for their respective journals in the metropolis are twice as numerous as the whole staffs of the London press." The general reader will find much to consider and to learn when he peruses this work. The information it contains is given in a clear and concise manner, and its literary articles on press work are of a higher order.

New Invention.

IMPROVED TONSIL GUILLOTINE.

THE insufficient removal of an enlarged tonsil when using "Mackenzie's guillotine" may depend upon want of dexterity in the operator, a defect which nothing but experience can remove. There are, however, conditions in the instrument itself which are calculated to frustrate the intention of the operator. In the usual instrument the handle is placed close to the end of the director or lower blade, so that when the knife is pushed home the driving thumb comes close to the grasping fingers, and the muscular mechanism of the hand establishes an arc of movement from the forefinger and hand towards the thumb, which causes the distal end of the instrument to diverge from right and left or from left to right, according as the right or the left hand is employed in operating. In other words, the instrument has a movement away from the tonsils

towards the middle line of the throat. This tendency may be obviated by placing the handle further forwards, and by making the knife itself at the same time longer, so that when it is pushed home an inch or so remains behind the commencement of the director. The result of this is that the main arc of manual motion is from the thumb towards the rest of the hand, and not *vice versâ*, and the distal end of the instrument moves towards, not away from, the tonsil.

Messrs. Arnold and Sons have constructed such an instrument for me, in which also the fenestra for admitting the tonsil is a large oblong, which may be diminished by pushing forwards the knife, the cutting edge of which is concave, not convex as usual. The shape of the fenestra has been modified in order to obtain as long an oblique diameter as possible, to enanare long and obliquely placed tonsils, which are not so easily included in the ordinary circular opening.

ALEXANDER MORISON, M.D, F.R.C.P.Edin.
Green Lanes, N.

PROPHYLAXIS OF INHERITED INEBRIETY.

AT the quarterly meeting of the Society for the Study of Inebriety held at 11, Chandos-street on Tuesday, 5th inst., Dr. Charles Hare presiding in the absence of Dr. Norman Kerr (to whose indisposition the chairman made feeling allusion), a paper was read by Mr. JAMES STEWART, F.R.C.P.Ed., of Clifton, who said they could not too often as scientific men protest against the use of the words drunkenness and inebriety as if they were convertible terms. M. Trélat had put the difference very clearly thus: "Drunkards are people who drink when they find any opportunity of drinking. Dipsomaniacs are diseased persons who get drunk whenever their attack seizes them." The drunkard, continued the lecturer, if he continues his vicious course might so injure his brain structurally or functionally that he would eventually become an inebriate. The inebriate, on the other hand, was an individual who was in most cases born with an unsound brain. He might even be a man who had never so much as tasted any alcoholic drink in his life. True, the disease might be acquired, but the experience of fifteen years had taught him that the neurosis was in most cases an inherited one. The neurosis often led the sufferer to seek relief by the narcotism of alcohol, and so cause and effect were greatly mixed up. Admitting, as they all must, that it was a transmissible cachexia, the question arises how best to prevent the germs of the inherited disease from being developed. Dr. Joseph Parrish had said "inebriety might descend as inebriety, but it was just as likely to change the form of its appearance into insanity or other allied manifestation." Bearing this in mind, it was important that the child of an inebriate should be kept free from what might upset the nervous equilibrium, care being specially taken that the surroundings during early years were bright and calculated to develop the higher and nobler characteristics of the individual. He deprecated especially corporal punishment at the hands of strangers. He advised the mother, if her husband had been an inebriate at the time of her child-bearing, to not only bring up her children absolutely as total abstainers, but, by telling them after puberty of their terrible inheritance, to warn them against ever touching alcoholic drink all their lives. The neglect to give this warning, the keeping back of this knowledge, had in some cases treated caused reproaches to be uttered against the mother for omitting to perform a duty to her child out of a desire to shield the memory of her husband. But if this duty was imperative in the case of a son, how much more so in the case of a daughter if either parent had suffered from the disease. If she is to marry, she ought to be warned as to the danger of marrying anyone whose family history was tainted with a neurotic inheritance—a danger enormously increased if she should marry a first cousin. The lecturer concluded by the following summary of his views: 1. Drunkenness is a vice, inebriety a disease; the two terms must not be confounded. 2. The disease of inebriety once established may be transmitted to the patient's offspring either in the form of the alcoholic diathesis, epilepsy, chorea, insanity, or even tendency to crime. 3. The child of an inebriate born after the functional or structural lesion has been established is sure to inherit some nervous diathesis. 4. The only security against this diathesis developing as inebriety is by life-long total abstinence on the part of the child. 5. Even the adoption of this precaution will not absolutely make certain that there will be no transmission of the cachexia by the child to his or her offspring. 6. To prevent the development of the alcoholic neurosis in other directions—such as epilepsy—sudden excitement of the emotions and sensibilities, such as might be produced by corporal punishment by strangers, should in all cases be guarded against. 7. In the prophylaxis of inebriety the principle to be acted on with regard to children's training is that if we accentuate the good we attenuate the evil. 8. The marriage of the child or even grandchild of an inebriate to a first cousin should be absolutely interdicted.

THE LANCET.

LONDON: SATURDAY, JANUARY 9, 1892.

THE gathering of the International Sanitary Conference, which opened at Venice this week, represents another attempt to arrive at some understanding as to the best method for preventing the extension of cholera to Europe. One of the main questions about which the Conference has to deliberate seems to be this: Whether ships coming from the East, and declared to be infected or only "suspect," shall be allowed to pass through the Suez Canal without being forced to remain there for days or weeks under observation or quarantine, provided that they are subjected to a strict supervision in the canal and prohibited from all contact with the shore as absolutely as if they were in an open arm of the sea. The Conference has been summoned on the initiative of the Austrian Government, and will take as its basis of discussion a protocol signed in London in July last by the Austrian Ambassador and the Marquis of Salisbury. This document deals with the measures to be taken by the Board of Health in Egypt in the quarantine question. Four-fifths of the vessels between the East and Europe are British. It is England consequently, with her system of commerce and troop service for India, that is most directly concerned, and it is probable that Germany, Austria, and Italy may support the views generally entertained in England.

The continental view is that cholera comes from India, that the Suez Canal is the portal by which it gains its entrance, and that all shipping should be dealt with there accordingly. England does not, through her scientific advisers, deny the possibility of the admission of cholera to Europe by the Canal route, but she can point to the fact that, although her own ships come through the canal year after year, in almost ever-increasing numbers, yet she has not imported cholera into Europe; and that if a real remedy is needed it is such terrestrial measures of prevention as will make the soil of Europe less ready to receive and to hold fast to an infection such as was imported from Tonkin on the occasion of the last epidemic. Those countries, the inhabitants of which do not care to spend much money in sanitary reform, would, of course, get off cheaply if their interests could be guarded by restrictions taken at Suez, and the burden of which would have to be almost exclusively borne by others than themselves. But, on the other hand, people who have willingly borne a vast expenditure in the amelioration of their own sanitary circumstances, hardly see why they should also be made to suffer again just as if they had been amongst the most neglectful of European nations. In this way two widely conflicting interests face each other at Venice, just as they did at Rome in 1885, but the Canal seems more than ever the central point of the discussion on this occasion, and the Foreign Office has now accordingly sought its principal counsellors amongst Egyptian officials. Mr. LOWTHER, new to office and new to the points in dispute, is, as British delegate, however, also accompanied by Mr. H. FARNALL, C.M.G., of the Foreign Office, and in his secretary Mr. LOWTHER will find one who is thoroughly conversant with every detail of the questions to be discussed, and who can weigh with judgment the respective merits of the various proposals which may be brought forward. Indeed, the secretarial position assigned to Mr. FARNALL may give him opportunities of making use of his very exceptional experience in regard to European cholera and quarantine, which he might have lacked had he been an actual delegate.

So many incidental interests are involved in anything relating to the Suez Canal that science can hardly be expected to find itself paramount in any conclusions that may be arrived at. Commercial, political, or financial considerations should not be permitted to dominate in a question of this kind. Our experience, observation, and the present state of our knowledge should be mainly consulted. Continental nations may freely assent to the view that the best safeguard against cholera, for example, is sanitation. But sanitation in an extended sense, and carried out as it is in England, means a very large expenditure of money such as only a rich country could afford, in addition to the expenditure of time during which the necessary public works are being constructed. Quarantine, isolation, and disinfection, it might be urged, are direct, immediate, comparatively easy of application, and cost relatively little. If it is not possible to remove the insanitary conditions necessary to the growth and development of a disease-cause, the best way is to strive to prevent its introduction. Unfortunately, however, experience has shown that all attempts hitherto made in this direction have been futile or impracticable. But we might go further. The Suez Canal has been open since 1869. The traffic between India and Great Britain has been enormous during the interval between that and the present time. It has often happened that cholera has prevailed in India, and it has occasionally happened that cases of cholera have occurred in ships leaving that country for England, but, as before remarked, there has not been one indubitable instance of a vessel passing through the Canal having introduced cholera and given rise to an epidemic or extensive outbreak of that disease in Egypt or this country since the Suez Canal was opened. As far as statistical evidence goes British ports have suffered almost nothing from cholera in comparison with other countries and places, and, as regards the recent history of cholera in Egypt, all the evidence points rather to Mecca pilgrimages than to the Suez Canal as its source. After all, we know too little of the real causes of many diseases to base practical action and legislation on such knowledge as we possess; but we do know a great deal about the effect of practical sanitation in safeguarding us against disease, and once we quit that we are apt to lose the foothold which fact and experience afford us.

Under all circumstances, the outlook at Venice is not, perhaps, as hopeful as we could have wished; and this the more so because whilst England has in reality been consistent in opposing cholera by sanitation in place of a failing quarantine system, she appears to foreign nations as

Digitized by Google

doing so only when she finds it answers her own purpose to adopt this alternative. The meeting-place is a favourable one, for the Government of Italy, who are acting as hosts, have shown themselves to be much in advance of many other European nations in regard to the true methods for preventing cholera extensions; and it is to be hoped that, under Italian auspices, some satisfactory conclusion may be arrived at.

THE researches of many inquirers working on such different lines as those afforded by the microscope, chemistry, meteorology, clinical medicine, and pathology, have shown incontestably that we are surrounded by multitudes of active and predaceous, if minute, enemies always ready to take advantage of any defect in our defensive armour, and to enter the system through every breach of continuity of the surface. Having once gained entrance, if the conditions be favourable to their growth and development, they rapidly multiply, and by their voracity as well as by their excreta soon destroy their host. The outworks of the fortress are extensive, the defenders are few and scattered, but active and capable of quick concentration. It may sometimes happen, therefore, that the numbers of the enemy admitted are insufficient to gain a footing, and, after a more or less severe contest, are overcome, their bodies squeezed and sucked, and then thrown out; or, on the other hand, it may happen that the garrison, tired and exhausted, or taken by surprise by a large body of the enemy, are unable to resist, and then utter rout and destruction are the result. The immunity that various animals possess against certain microbes has been the subject of a lecture in THE LANCET of Dec. 26th, 1891, by Dr. ARMAND RUFFER, and of a paper by the same author which appears in the volume for 1891 of the *Quarterly Journal of Microscopical Science*. It is here pointed out that, though denied by competent bacteriologists, overwhelming evidence has accumulated showing the influence of numbers. Thus 250 millions of staphylococci injected into a rabbit will produce an abscess in this animal, but 1000 millions of the same parasites will cause death. A few drops of a culture of the bacillus pyocyaneus injected into the veins of a rabbit give rise to a chronic disease, whereas a quarter of a cubic centimetre of the same culture kills the animal with certainty. The nature or virulence of the microbes introduced, the animal experimented on, and the mode in which the introduction is effected—as, for example, into the blood itself or into the subcutaneous connective tissue,—are all circumstances that materially modify the result. Still, it is interesting to inquire by what means the injurious effects caused by a minute quantity of the poisonous fluid injected are prevented, when it can be easily demonstrated that a slightly larger quantity proves fatal. Dr. RUFFER first discusses the cases in which guinea-pigs have been inoculated with the virulent disease named "quarter-evil," produced by the bacillus Chauvœi, to which disease, unlike rabbits, they appear to possess a remarkable proclivity. If a small quantity of the powdered virus be introduced under the skin, a small hard swelling appears at the seat of the wound in from twelve to eighteen hours; crepitation is felt, with thickening of the surrounding parts. After twenty-four hours the animal shows evident signs of sickness, becomes lethargic, droops and dies in the course of forty-eight hours after the inoculation. On examination, the remains of the powder are found lying in a cavity lined by a thin grey fibrinous layer and containing fluid. The surrounding muscles are œdematous. Now, if twelve hours after the puncture a little of the transparent fluid in the cyst is drawn off, it is found to contain a large number of bacilli, which move in the liquid. The leucocytes are few, and are either empty or occasionally hold two, three, or more bacilli in their interior. Forty-eight hours after the puncture, or just after death, the fluid contains immense numbers of bacilli and many leucocytes. These are of the small variety of amœboid cells named microphages, and many of them contain bacilli. The abscess walls present on their free surface a dense mass of similar amœboid cells, the bacilli in the interior of which frequently show signs of degeneration, staining less uniformly and deeply than the bacilli which still remain outside the microphages, becoming smaller, and ultimately breaking down. Large numbers of bacilli exist outside the leucocytes. We may suppose that in such a case the fight between the microbes and the leucocytes ends in the discomfiture of the latter, and death results. If, however, a small dose of a weak virus be inoculated subcutaneously, the struggle between leucocytes and bacilli is evident up to the fifth day, or even later; but the number of micro-organisms gradually diminishes, so that after the fourth day hardly any bacilli are found at the seat of inoculation. On the fifth day the few bacilli which can still be seen are contained in migrating cells, and show evident signs of the most advanced degeneration. In such a case the contest between the microbes and the amœboid cells terminates in favour of the latter. Similar facts have been observed in the erysipelas of man, and Dr. RUFFER in two fatal cases found numerous streptococci in the lymphatic vessels, in the skin, and in the layers immediately beneath, but always outside the vessels; innumerable leucocytes had emigrated to the spot. In other cases which ended in recovery many of the migrating cells were absolutely crammed with micro-organisms, forming a mass surrounded by a clear vacuole in the interior of the leucocyte. Analogous conditions were found in cases of swine fever and in cases of anthrax. There seems to be no doubt that the bacilli are ingested by the leucocytes in the living state, since after the death of the leucocytes the bacilli, if placed in favourable conditions, begin to develop. But another observer (Dr. ROGER) has made the interesting observation that the serum of guinea-pigs which are non-immune against the bacillus Chauvœi possesses very strong bactericidal powers on this organism; whereas the serum of rabbits which are relatively immune has no harmful action on it. This observation is in favour of Dr. RUFFER'S view that the bactericidal powers of the *dead* fluids of any animal against a specific micro-organism is no criterion of the power of resistance of that animal against this micro-organism. Finally, there seems good reason for believing that the chemical poisons secreted by micro-organisms attract the leucocytes to the spot where they are introduced.

DESPITE the fact that the fog question has been discussed over and over again by eminent authorities and experts, no practical solution of the difficult problem has as yet been arrived at. Indeed, it is open to grave doubt whether any

Digitized by Google

of the many proposals that have been made could be really carried to a practical issue, or would be followed up with any measure of success. The adoption of smokeless stoves has been thought to be a means of grappling with the intolerable nuisance, but to carry out this scheme in a large city like London would clearly involve an immense outlay of money, and the difficulties which would obviously attend the introduction of the smoke-consuming stove in the place of that used in almost every house in the metropolis at the present time would appear to be well-nigh insurmountable. Even supposing, too, apart from this, that every stove in London did effectually consume its own smoke, nothing can alter the climatic conditions which must inevitably produce what, for the sake of distinction, we call mist. London is just as liable to the formation of mist as the English Channel or the open country; and granting that coal is perfectly burnt, how far, it may be asked, will perfect combustion affect the character of the well-known pea-soup variety? From the nature of the constituents of coal, we know that if it is completely burnt in air nothing but invisible gases, consisting mainly of carbonic acid, water, and sulphur dioxide (or sulphuric acid, $H_2O + SO_3$), as we have generally found, should be obtained, together with a perfectly white ash, representing the mineral contents. As long as coal therefore is our source of fuel, however perfect the method of consumption may be, there must result *a priori* the products just enumerated. Are these products deleterious, or at any rate as prejudicial to health as those which have been shown to occur in fog deposit? The analysis of fog deposit collected at Kew, an account of which appeared in THE LANCET of August 15th, 1891, page 390, showed it to consist of 42·5 per cent. carbon, 4·8 per cent. hydrocarbons and organic bases (pyridines), 4 per cent. sulphuric acid, 0·8 per cent. hydrochloric acid, 1·1 per cent. ammonia, 41·5 per cent. mineral matter, and 5·3 per cent. moisture. A deposit collected in Chelsea consisted of 39·0 per cent. carbon, 12·3 per cent. hydrocarbons, 2 per cent. bases (pyridines), 4·3 per cent. sulphuric acid, 1·4 per cent. hydrochloric acid, 1·4 per cent. ammonia, 2·6 per cent. iron and magnetic oxide, 31·2 per cent. mineral matter, and 5·8 per cent. moisture. The amount of deposit collected was equivalent to six tons to the square mile. From this it appears highly probable that the character of fog would, by the adoption of smoke-consuming stoves, be changed for the better, and be reduced to the less injurious condition of mist. The substitution of invisible carbonic acid, water, and small quantities of sulphuric acid for visible and colour-producing carbon, organic bases, pyridines, and various mineral matters would, it is safe to assume, be far preferable. Carbonic acid and water, both the normal products of oxidation in the animal economy, can hardly be said to possess properties of a particularly noxious character, although exception might be taken to sulphuric acid. The production of this acid is inevitable so long as coal contains sulphur. Probably, however, it could be removed by the adoption of a simple arrangement similar to that used in gas works for purifying foul gas. Lime or any of the alkalies readily absorb this acid. There seems to be no reason why a few shelves or drawers arranged in dovetail order containing either of these substances could not be constructed at some convenient place in the chimney. The absorbent could be renewed from time to time, just in the same way as at present the chimneys are periodically swept out.

There is much to be said for and against the scheme which proposes to introduce the exclusive employment of gaseous fuel. One common obstacle to the introduction of this and to most other schemes—and by no means one easy to remove—is that of sentiment. There lies in the glowing coals a virtue which a mere heat-giving body cannot possess, and the mysterious reflections and fancies conjured up when—in an indulgent reverie—one peers into the incandescent depths, can never be derived from a gasburner or the closed and dead-looking stove. This sentimental objection is no doubt a strong one to remove, and inventors would perhaps do well to give their attention to a method which shall provide for the removal and utilisation of the products of incomplete and imperfect combustion as they are met with in the ordinary domestic fireplace of the present day.

UNDER the name of "Onomatomanie," MM. CHARCOT and MAGNAN have recently described some curious forms of functional derangements of the faculty of speech. These derangements occur in certain neurasthenic patients, and are quite distinct from any variety of aphasia or aphemia. M. SÉGLAS of the Salpêtrière, in a recent paper, describes five varieties of the affection. In the first, the chief feature is an agonised effort to recall some word; in the second, the sufferer seems possessed by some word, and under an irresistible impulse to go on continually repeating it; the third variety is characterised by the patient attaching some peculiar and dreadful meaning to some commonplace word; in the fourth, the patient attaches some talismanic influence to certain words, and goes on repeating them as a safeguard to himself; while in the last variety the individual is impelled to, as it were, spit out some word, like a disgusting morsel. According to M. SÉGLAS, a word is "a complexus of images, localised in certain centres of the cerebral cortex, the images being partly auditive, partly visual, partly motor. Thus, the characteristic feature of "onomatomanie" is just the irregular action of one or several of these verbal images, resulting from some functional disturbance of the corresponding centre."

In what is called simple "onomatomanie" the chief feature is that the patients are generally possessed with the idea of recovering a word which escapes them. Although the word is quite familiar to them, although they can give its signification, state the place where they have read it or the moment at which they have heard it, they appeal vainly to their memory to recall it. The result is an agonised effort to recall the word, and presently the patient hears, as it were, the word vibrating at his inner ear, and he becomes calm again. In another variety of the affection it is the articulate part of speech which is at fault. The patient knows the word, sees it written, as it were, visibly before him, but is quite incapable of articulating it. Perhaps he utters some synonym of the word or some word resembling it in certain letters, until suddenly the word is found and the painful crisis ends. More curious still are those cases in which the patient seems possessed by a word as if by a demon. Sufferers state that they hear the word constantly resounding in the head, or sometimes the word seems to

Digitized by Google

fade away in a sort of distant echo. The attacks may come on each time the patient meets certain words in reading or hears them accidentally pronounced. M. SÉGLAS mentions the case of a woman who each time she met the word "rage" seemed to feel the word persisting before her eyes. Such cases shade off into cases of genuine hallucination, in which the patient hears imaginary words constantly sounding, or sees them written in the air. Other patients are tortured by the fear of uttering gross or compromising expressions, and often ask the bystanders what they have just said. Others, again, present the symptom of "echolalie" or imitative speech, and go on repeating words like a phonograph.

A second distinct variety of the affection is described under the term of "onomatomanie associée," which includes those cases in which certain words acquire some peculiar and preponderant meaning in the eyes of the patient. He may regard some word as noxious and disgusting, to be got rid of by a violent expulsive effort, or he may look on some word as possessing the power of shielding him from hurt and mischief. A case is cited of a patient who could never hear the words "vendredi," "malheur," "treize," without at once correcting their supposed injurious meaning by pronouncing the words "samedi," "bonheur," "quatorze." Some patients have the idea that it is some enemy who has the power of making them hear and repeat the disquieting words. What distinguishes "onomatomanie" from ordinary cases of auditory hallucination is the occurrence of the crisis of agonising effort, and the calm which follows when the crisis has been surmounted. It must be observed that the mere verbal features of the affection would be insufficient to distinguish it. As regards the prognostic value of the various forms of "onomatomanie," M. SÉGLAS is of opinion that the outlook is most grave in those cases in which the language troubles seem to depend upon an erethism of the motor centres exaggerating the intensity of the motor images, and impelling the patient to an irresistible impulse to expel the word. This last symptom, he believes, denotes a cerebral disintegration characteristic of the worst forms of intellectual decline.

The above description will, we imagine, be new to many of our readers. It must be observed that while some of the cases adduced in the earlier part of this article bear a considerable resemblance to some cases of aphasia, they occur apart from any paralytic or hemiplegic condition, and simply in neurasthenia. Other cases seem to border on true hallucination, but the accounts of our French contemporaries would seem to establish the genuine existence of an intermediate class of case, distinct alike from aphasia and insanity, and the recognition of this group under a distinctive name would be a real gain to pathological literature. The subject abounds in difficulties, which is not surprising when we recollect how complex is the machinery employed in language, and how many factors, physical and psychical, unite for its production.

SIR ANDREW CLARK has done good service to the cause of medical education by undertaking a course of clinical lectures on Common and Functional Diseases, the introductory lecture of which, on the Methods of Clinical Instruction, we published last week. The moment is opportune. This is New Year time in a special sense with medical education. From the beginning of 1892, by recommendation of the General Medical Council, an additional year will be added to the term of study required of medical students. On June 5th, 1890, the Council adopted the following resolution of its Education Committee: "(*a*) That the course of professional study after registration should occupy at least five years *conditionally*," and one of the chief *conditions* is specified by the Council in the following recommendation: "(*d*) That the fifth year should be devoted to clinical work at one or more public hospitals or dispensaries recognised by any of the medical authorities mentioned in Schedule A of the Medical Act, 1858, provided that, of this year six months may be passed as a pupil to a registered practitioner holding a public appointment, or possessing such opportunities of imparting practical knowledge as shall be satisfactory to the medical authorities." Recommendation (*g*) requires every candidate for the final professional examination at the end of the fifth year to give evidence that he has had sufficient opportunities of practical study &c. Recommendation (*h*) provides that the regulations of schools and examining bodies be so framed that attendance on systematic lectures shall be concluded at the end of the fourth year, so as to permit of the student devoting the fifth year to clinical work as defined in recommendation *a*. Recommendation (*i*) requires that, with the view of securing attention to practical work in education, the time devoted to the practical part of the examinations in all the subjects shall be extended.

Such resolutions, in their spirit and in their letter, mark an era in medical education. In other words, they indicate a determination on the part of the General Medical Council to insist on the *clinical* element in teaching, to bring it to a practical issue, and to send out young men from the schools familiar with disease as they are likely to meet with it, and fit for the duties and responsibilities of practice. In these circumstances nothing could be more seasonable than the address of Sir ANDREW CLARK, in which he expounds, with his usual clearness, the different methods of instruction in such matters, and ends with a preference worthy of GRAVES or of LATHAM. It might have been otherwise. Sir ANDREW CLARK is more than a mere physician. He has powers of the dialectic and of the didactic sort, in the use of which he excels. Systematic exposition and moral reflections are in him such powers as great preachers or orators might envy. But he represses all these and elects to use the hour which he is to steal from his busy life to show the students of the London Hospital the plain art of seeing a patient in the most considerate and humane way, and finding out readily and shrewdly what is the matter with him, how his health can be restored and placed on sound physiological lines for the future.

"My object is not the delivery of didactic lectures, not the reading of clinical essays, not the demonstration of technical proceedings, and not the discussion of rival pathological theories. All these procedures have their time and use. My one object now is to help you to get plain

Digitized by Google

practical clinical instruction, and so to get it of such a kind that you may pass from this hospital into practice accustomed to its methods and cautions, without fear of disaster and ready for sound and honest work."

These are timely and weighty words, alike loyal to the spirit and the letter of the recommendation of the Medical Council, and kind to his students. He is not only going to teach clinically, but he is going to show to his students his own method of seeing patients, and his own way of eliciting the truth as to their case and wants. He is not going to mumble out a few broken sentences after hearing the report drawn up by the clinical clerk, but, coming fresh to the consideration of the case of the patient, he is going to make him tell his own story and his family history; then using the proper methods of investigation and instruments of diagnosis, he will form his opinion of the case, its proper treatment and its probable course—all to be done with due regard to the feelings of the patient. In other words, he is going to act the part of a practitioner in daily practice examining cases functional rather than organic, chronic rather than acute, common and ordinary rather than exceptional. An example so good by a teacher so authoritative cannot fail to be extensively followed by other teachers. He expresses no opinion on the difficult question of pupillage. But he admits that while ample provision is made in medical education for the study of the graver forms of disease, acute and chronic, substantially no provision exists for the study of the slighter forms of disease or of disease in its earlier and more curable stages, beyond the necessarily oftentimes incomplete lessons afforded by the out-patient department. Such a statement comes very near an admission of the necessity for lessons in general practice. There are large classes of cases in general practice which cannot be seen in their continuity elsewhere. The claim of the general practitioner to be a teacher might have to be determined by the examining authorities, one of whose functions it is to recognise hospitals or schools. But if students are to study cases that are scarcely seen in hospitals, and cases that largely make up general practice, and to study the art of seeing them and dealing with them promptly and practically, it is difficult to deny a place in the curriculum for lessons in general practice. We do not here propose to go further into this question, but content ourselves with thanking Sir ANDREW CLARK for his powerful exposition of a defect in medical education, and for giving the weight of his personal example in favour of the best of all kinds of clinical instruction, enabling those who receive it to enter practice "without fear of disaster and ready for sound and honest work."

Annotations.

"Ne quid nimis."

THE ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

IT gives us great pleasure to inform our readers that the Lord Mayor of London has consented to take the chair on April 5th at the dinner in aid of the Pensioners and Foundationers Fund of this College. It is peculiarly fitting that his lordship, a resident near the College and a Welshman, should consent to come forward to assist the great work of his fellow countryman, John Propert. It is necessary to find between £5000 and £6000 annually to meet the expenses of the charity, and the yearly income from its small capital is only a few hundreds. Pecuniary aid is therefore urgently needed to meet these demands, and this year a strennous effort will be made by the Council to place the condition of the pensioners on a more satisfactory footing. Of late years public opinion has recognised how far greater a charity it is to give even a moderate pension to the aged and to the needy, and to enable them to spend their declining years with their relatives and friends, than to give them a smaller income and residence in a fixed situation—too often at a distance from anyone they have known. The Council will again appeal most earnestly for help to capitalise such an amount as will enable them to give the pensioners augmented incomes in lieu of residence, and to allow them to live where they please. In this connexion it may be remembered that on the occasion of the last biennial festival, which was fully reported in THE LANCET of April 26th, 1890, we stated that we considered this suggestion so admirable that we had written to Dr. Holman, the treasurer, to say that "providing £49,000 be collected within two years from the present time, we will give the other £1000 to make up the amount he asks for; or, in the event of that not being accomplished in two years, we will subscribe an amount in a similar proportion to the sum actually collected." No aid is asked for the school, which has so often erroneously been termed a charity school, although Section 28 of the Act of Parliament proves that this was never contemplated. It is full to overflowing as a result of its high repute for tone and good work. Success, indeed, presses so hard that increased accommodation is urgently needed. A double advantage will eventuate from a greater charity to the pensioners: the Asylum can be most usefully employed in meeting the demand for increased school accommodation. The wishes of the founder will assuredly be carried out by a more generous treatment of the aged and of the poor; and the dream of John Propert that Epsom might one day rank high amongst the schools of England bids fair to be realised.

INFLUENZA.

THE past week has been marked by a rapid extension of influenza, both in this country and abroad. It has also been notable for the announcement from Berlin that Dr. R. Pfeiffer has discovered in the sputa of patients suffering from the affection a bacillus which he believes to be pathogenically related to the disease. In this connexion it may be well to call to mind the former discovery by Dr. Jolles of Vienna, two years ago, of a microbe in influenza which was suspiciously like Fraenkel's pneumococcus. Still, as there is *a priori* ground for believing that influenza is a microbic affection, we must await fuller details of Dr. Pfeiffer's research before passing judgment upon it. Although the discovery, if confirmed, will advance our knowledge of this mysterious plague, it cannot be expected to influence the lines of its treatment very materially; and it is quite unreasonable, as some are doing, to reproach the profession for not having ere now found a specific remedy first, seeing that there is no infective disease known for which it can be said that we possess a true specific. The laity may feel assured that the treatment of influenza is carried out on rational principles. It is noteworthy that, when the numbers attacked are considered, the mortality rate is lower than that from almost any other known specific fever. As regards the parts of this country which are now the chief centres of the epidemic, it is noticeable that the southern, eastern, and midland counties are those where it most prevails. The Scilly Isles have been visited severely by the epidemic, which still exists to a great extent in South Devon, and has been especially rife at Tiverton. In Dorsetshire the agricultural

Digitized by Google

population is widely attacked. In Hampshire influenza is very prevalent at Southampton and the vicinity. In Berkshire, Windsor, Reading, Newbury, and the country around have been severely visited. In Surrey it has prevailed at Walton, Kingston, and Richmond. In Sussex cases have occurred at Horsham, Worthing, and Brighton. But it is in Kent, as noted last week, that its ravages have been most severe, particularly at Canterbury and the Ashford district, where the authorities have followed the example of Dover in imposing a penalty for wilful exposure of patients. North of the Thames influenza has gained a firm foothold in Essex, where numerous cases are occurring in the villages and smaller towns, Bishop's Stortford and Dunmow being specially mentioned. In Herts cases have occurred at Luton, Dunstable, and St. Albans, and the counties of Cambridgeshire, Huntingdonshire, and Northamptonshire are all being invaded. At Hucknall Torkard in Notts there have been many cases. In Suffolk and Norfolk it is also very prevalent. In fact, the disease is spreading over the land quite as markedly as at its previous visitations. It has certainly become more prevalent in the metropolis, where last week the number of deaths directly attributed to it rose to 37 from 19 in the preceding week. The mortality from diseases of the respiratory organs (for which the previous week of fog was largely responsible) rose to the enormous figure of 1317, exceeding the corrected average by 778. The general death-rate in London was as high as 42 per 1000, being only exceeded among the large towns by Liverpool (42·2 per 1000) and Wolverhampton (45·3 per 1000). Influenza seems to have disappeared from Scotland, except in the remote Orkneys, where it has been recently raging; and in Ireland Limerick and Newry have been the chief centres. On the Continent it still prevails in France, and among its victims has been Professor Charcot, who, we are glad to learn, is now convalescent. In Italy it is especially rife at Milan, but has occurred in many other towns, as Florence, Begamo, Turin, and Genoa. In Austro-Hungary the outbreak at Buda-Pesth has been exceptionally severe, and the disease is prevailing in Styria and elsewhere. There is less mention of its spread in Germany; but it has been very prevalent in Belgium, among the sufferers being the King of the Belgians and the distinguished political economist, M. de Laveleye, who succumbed to the disease. The lunatic colony of Gheel has been ravaged by the epidemic, the mortality being very high indeed. At Malines work has been almost suspended by the plague. From Russia comes the intelligence that the Czarina has been attacked; but we have no definite information of the spread of the disease in that country. In other parts of the world information comes of its occurrence in two opposite quarters of the globe—namely, in Tonquin in the far East, and in British Columbia and Vancouver in the far West, the native Indians especially suffering in the latter countries. In conclusion it may be noted that influenza and "pink-eye" have been very rife among the horses at the South Yorkshire collieries, whilst concurrently with the influenza epidemic in Dorset "pink-eye" has prevailed among the farm stock, and the same affection is also prevalent in the farms of South Bedfordshire.

THE JEALOUSY OF THE PEERAGE.

THE new year's list of honours is thin and poor, as far as science is concerned. The gift of a peerage to Sir William Thomson, indeed, is an act which redounds highly to the credit of those who advise Her Majesty, but it is late, and is almost the first recognition of the sort in this country which is generally supposed to lead in liberal ways and generous recognition of merit. The deserts of the medical profession are met, according to this test, in the gift of a C.M.G. to P. D. Anthonisz, M.D., of Ceylon. The House of Lords will receive as much honour as it will confer in the elevation of Sir William Thomson, and we cordially recognise in this step an indication that Lord Salisbury wishes to make the second chamber something more than a mere collection of hereditary legislators. Perhaps he is not to blame for the halting manner in which the need for reform is recognised; but somebody is to blame, and whoever it be he is no friend to the House of Lords. We shall say little about the continued exclusion of representative men of our own profession from the House of Lords; but we think the more. The Upper Chamber will never be what it ought to be till it includes men of light and leading from all the liberal professions.

"RURAL DEPOPULATION."

THE rapid increase of our urban communities and the slow and declining rate of increase of our rural population during a long series of years are of the deepest nterest from a public health, as well as from a social and political, point of view. It is, however, manifestly incorrect to speak of this constant migration from country to town as "rural depopulation," by which term it is so generally described by the newspaper press. The inaccuracy of the use of this term was insisted upon by Dr. Ogle in a paper on the subject read a year or two ago before the Royal Statistical Society. The Preliminary Report on the Census in April last showed that while the population of the 1006 urban sanitary districts had increased by 15·3 per cent. between 1881 and 1891, the increase in the remainder or rural portion of the population of England and Wales was only 3·4 per cent. It is obvious from these figures that the rural districts during the last intercensal period lost by migration to towns or by emigration beyond the seas a very large proportion of their natural increase during the ten years by excess of births over deaths. It is, however, at the same time obviously inaccurate to talk of the depopulation of our rural districts when their population in 1891 exceeded that in 1881 by more than a quarter of a million. There is another point in connexion with the light thrown upon this important subject by the results of the recent census, to which attention was recently called in the columns of THE LANCET, but which is lost sight of by most of those who write concerning this so-called rural depopulation. We pointed out that in those rural counties in which the population has recently been actually declining the rate of decrease was smaller in 1881-91 than it was in 1871-81; while in the rest of the rural counties the rate of increase, although very low compared with the rate of increase in towns, was higher in 1881-91 than in 1871-81. A recent correspondent in a contemporary was inaccurate when he wrote of "the decrease of population in rural districts shown by the recent census," for, speaking generally, there has been an increase of 3·4 per cent. instead of a decrease; he was, however, still more markedly inaccurate when he referred to the evidence afforded by the agricultural returns of the cause of this decrease, which decrease is disproved by the census returns. The decrease of the English population engaged in agriculture between 1871 and 1881 was partly attributed by the census commissioners in their report to the decrease of arable land and the consequent increase of permanent pasture. The same correspondent asserts that "no very great acreage that was under tillage has been laid away to grass." This assertion is too general in form to controvert, but when he adds "in point of fact the acreage under grass of all kinds in Great Britain has only increased 9·1 per cent. during the last twenty years," and supports this assertion with figures, it becomes evident that his ratio of increase is miscalculated. His figures show that, in 1871, 54·5 per cent.

Digitized by Google

of the acreage of Great Britain was under grass, while in 1891 the proportion had increased to 63·6 per cent. of the whole. These figures indicate that of each 100 acres in Great Britain the number under grass in 1891 exceeded the number in 1871 by 9·1, but it is obviously incorrect to say that "the acreage under grass of all kinds in Great Britain has only increased 9·1 per cent. during the last twenty years," since the increase of 63·6 upon 54·5 is equal to 16·7 per cent. Indeed, if the proportion under permanent grass be taken alone, the amount of increase in the twenty years is no less than 23·2 per cent., although in each 100 acres there were only 9·2 more under pasture in 1891 than there were in 1871. This is not the place to discuss the causes of the constant migration from rural to urban districts, but the facts referred to above appear to warrant the conclusion that if this migration be in great measure due to the higher wages and general attractions of town life, these causes are accentuated by the depression of agricultural interests, one of the signs of which is the increasing acreage laid down in permanent pasture leading to a most important reduction in the demand for farm labour.

THE LANCET RELIEF FUND.

THE "Application Form" of THE LANCET Relief Fund will be found in our "General Advertiser" columns. It can easily be removed, filled up, and forwarded to the Secretary, Mr. Edward Davies, THE LANCET Offices, 423, Strand, London. We would once more ask those of our readers who may have occasion to employ the form, or to sign one of the required accompanying certificates, to carefully notice the conditions on which applicants become entitled to a participation in the benefits of the Fund.

DEATH UNDER CHLOROFORM.

WE are able to give the following facts concerning the case which proved fatal at the Middlesex Hospital on Dec. 19th:—The patient was a carman, aged forty-seven, to whom an anæsthetic was administered for the purpose of discovering the cause of a considerable loss of blood from the bowel. The patient was a man of large frame and full habit; he was said to be much addicted to drink. His chest was very barrel-shaped, and the lungs markedly emphysematous. Chloroform was administered by means of Krohne and Sesemann's modification of Junker's inhaler, with patent respiration indicator. He took the anæsthetic well, and passed through the stage of intoxication, the face becoming slightly congested, but not livid. At about four minutes after the commencement of the administration he was wheeled into the theatre and lifted on to the operating table, the administrator closely watching the respiration and pulse all the time. The respiration then suddenly stopped without the slightest warning, though the pulse for a time continued to beat regularly. Despite every effort at restoration the man never rallied. Directly the breathing stopped the head was hyper-extended and the tongue drawn forward; forcible pressure was made once or twice on the sternum, and Silvester's method of artificial respiration was resorted to, though this, owing to the rigid state of the thorax, produced but little flow of air. Tracheotomy was therefore quickly performed and air pumped into the lungs. Howard's method of artificial respiration was also tried, but was found to be less efficient than Silvester's. Inversion combined with artificial respiration was also resorted to, and these, together with minor measures, such as enemata of brandy, injection of ether, hot fomentations over the heart, exhibition of nitrite of amyl, free supply of fresh air, &c., were continued for over an hour without the slightest effect. The necropsy revealed firmly adherent and extremely emphysematous lungs and a greatly dilated thin-walled heart infiltrated with fat, the right cavities being full, the left empty. The cause of the rectal hæmorrhage appeared to be a general capillary oozing, and this had been so extensive that the man would probably have died in a few days. It is difficult to arrive at the true explanation of any case of death from chloroform; in this instance it is probable that the lungs, being extremely emphysematous and adherent to the chest wall, contained a large amount of residual air, which became saturated with the chloroform vapour, and the latter, becoming absorbed, suddenly paralysed the respiratory centre. Owing to the pathological condition of the lungs, and to the conformation and rigid state of the thorax, the vital capacity, and therefore the power of elimination, was extremely small, and artificial respiration was correspondingly difficult. The amount of chloroform used was carefully observed, and it is stated to be under one drachm.

THE ENLARGING NUMBERS OF THE PROFESSION.

WE shall have to wait some time for the official Register of the profession. Meantime we are very thankful for Churchill's Directory which gives us early information of the numbers of the profession. According to this authority there is no check in the rush into our already overcrowded ranks. The explanation of this increase cannot be found in a desire to evade the regulation extending the curriculum to five years, for this regulation has not been passed long enough to affect those registering last year, and whose registration would seem to add no less than 551 to the total of the profession. The numbers given for the two years 1891 and 1892 are as follows:—

Number of Practitioners.

	1891.		1892.		
London	5095	....	5293	....	+ 198
Provinces..	13,926	....	14,026	....	+ 100
Scotland	2739	....	2850	....	+ 111
Ireland	2489	....	2445	....	- 44
Resident Abroad	2795	....	2962	....	+ 167
Naval, Military, and Indian Medical Services, and Mercantile Marine	2440	....	2410	....	- 30
"Too Late" List—Additional names*..	—	....	49	....	—
Total	29,484		30,035		+ 551

* Not given in 1891.

From these figures we gather that the augmentation increases. "The rain it raineth." For whereas between the years 1890 and 1891 there was only an increase of 112, between 1891 and 1892 the addition is 551. There are some changes in the arrangement of districts. Thus London now includes the following places:—Chingford, Chiswick, Edmonton, Gunnersbury, Leyton, Manor-park (Essex), Merton, Tottenham, Turnham-green, Walthamstow, Wimbledon, and Woodford.

THE RE-INFLATION OF A LUNG FOR ISLINGTON.

ACCORDING to recent information there is now in Islington a chance for the good offices of the Metropolitan Public Gardens Association. It appears that the vestry, after long delay, and at the instance of the County Council, have decided to reorganise, by extensive demolition and otherwise, the little slum district known as Norfolk Area. The spot in question is, in its way, an interesting relic of rural Islington, a village fragment which has become on all sides hemmed in by the backs of back streets, themselves respectable at least in age. It consists of small, old-fashioned houses, for the most part whitewashed, and arranged in two squares, each having its plot, once a garden, in front. Thanks to their distribution in this order, ventilation of the space is far from hopeless, notwithstanding its imprisonment by surrounding brick and

Digitized by Google

mortar, and the roadway is cleanly enough kept. The buildings themselves, however, have become superannuated, and it was hardly to be expected that their internal defects could long escape or could ever satisfy the fiery eyes of modern sanitation. Its light has penetrated their ancient recesses, and the vestry, its minister, has condemned them. The squares, rustic no longer, will probably be traversed by a new road, and certainly there can be no objection to this, though it seems hardly needful to add a spacious thoroughfare to others already existing close at hand, nor is it easy to see how the whole of the available space can be thus utilised. A passage connecting two or more of the adjacent streets would satisfy the requirements of pedestrians, and the rest of the area might well be converted into a small common green or playground for the children of the district, with back-door communication for the surrounding houses if desired.

CEREBELLAR TUMOUR.

DR. HOWARD publishes in the *Australian Medical Journal* the case of a patient who had been under his care suffering from cerebellar tumour. The patient was a woman of forty, who for six months before her confinement in December had suffered from headache, giddiness, and unsteadiness in walking. Her symptoms became aggravated after her confinement; she staggered in walking, being inclined to fall to the left side. She had severe headache, worse in the occipital region to the right of the middle line. There was no actual paralysis, her knee-jerks were normal, and there was no change in the optic discs and fundi except some venous engorgement. Death took place suddenly, and at the necropsy a round tumour was found arising from the back of the inferior vermiform process of the cerebellum, and growing forward so as to fill all the front part of the fourth ventricle. The tumour was an inch and three-quarters long and an inch and a half broad, and in structure was a mixture of glioma and sarcoma.

THE TREATMENT OF DIPHTHERIA.

To what extent principles of treatment of cases of infective disease may be modified by the acquisition of true knowledge concerning the nature of such affections is well shown in a paper read recently before the Clinical Society of Paris by M. Barbier, in which he dealt with the subject of diphtheria (*La France Médicale*, Jan. 1st, 1892). He pointed out that the researches of Klebs, Loeffler, Roux and Yersin, and others have now conclusively established that the pathogenic agent is a bacillus which is only to be found in the false membranes and does not penetrate either the blood or tissues. That discovery decides the much disputed question of the "local" or "general" nature of the malady. The "false membrane *is* the disease," and the primary object of all medication must be to detach and remove it wherever it is accessible; for one removes thereby not only the morbific agent, but the toxalbumens which the microbe elaborates, and which are the source of the symptoms. But experiment also teaches that the bacillus does not develop on healthy or non-excoriated mucous membrane, and it is therefore of chief importance that the false membrane should not be detached violently, but gently and slowly. Cotton wool held in forceps gently and with frequent patient repetition brushed over the false membrane will gradually detach it, but care must be taken not to touch any other part. This is the first step. The next is to apply to the affected area such an antiseptic solution as has been proved by experiment to destroy the bacillus. Under M. Grancher, M. Barbier had largely studied this subject experimentally, and found carbolic acid to be the best parasiticide for this purpose; and he now recommends the application of a mixture of sulphovicinic acid (100) and carbolic acid (20) as more efficacious than carbolic acid and glycerine or olive oil, as hitherto adopted. This "*phenol sulfovicinè*" causes a transitory sensation of heat and burning, but its taste is not very pronounced, and, he says, children tolerate it well. Moreover, although frequently applied—every hour by day, every two hours by night—M. Barbier has never seen any sign of carbolic poisoning. Before applying it each time there should be practised free irrigation of the naso-pharynx, which aids in detaching more membrane, the warm water being rendered antiseptic by the addition of a small quantity of an alcoholic solution of salol (1 in 40). He claims for this procedure, vigorously carried out, a marked amelioration in the more serious signs of infection—the redness of the throat, glandular swelling, constitutional symptoms, and albuminuria. Similar principles he applies to the after-treatment of tracheotomy in laryngeal diphtheria; and he advises the prescription of calomel and naphthol to promote intestinal antisepsis rendered necessary by the swallowing of portions of membrane detached from the fauces. Then general tonic treatment, with plenty of fresh air and sunlight, and avoidance of close rooms and steam. He gives no statistics, but he claims to have seen many good results from adhering thus rigidly to the teachings of the laboratory; and certainly there is no greater field for the study of diphtheria than the Paris Hôpital des Enfants Malades, where M. Barbier's observations have been made.

SOCIAL GATHERINGS AND PREVAILING SICKNESS.

WE are not going to make ourselves disagreeable by offering any unreasonable objections to the usual juvenile parties of the season; but we cannot forbear a word of monition on the subject. Schools when reassembling require certificates from the pupils that they have been free from exposure to infectious disease. It would scarcely do to add a postscript to an invitation to the effect that the guests must fortify themselves with a similar certificate. But surely some understanding should be arrived at that persons having been lately exposed to infectious disease in their houses should, for the public good, decline to give their friends the pleasure of their company. If this be not done, New Year and other parties may become a great engine for the multiplication of regrettable cases. A little candour and unselfishness in such matters are high virtues.

ARMY RECRUITING.

THE committee appointed to consider the question of recruiting for the army has now been engaged for a considerable time. A large amount of evidence has no doubt been taken, and we may presume that the committee must by this time be discussing and deliberating about the nature of their report. The task is obviously a very difficult one, and we are afraid it will not be much facilitated by all the discussions that have taken place of late about our military organisation and administration. We gather from it all, however, that there seems to be a general agreement on two points, and on two points only—viz, that our army abroad, in India and elsewhere, is satisfactory, and in an excellent condition of physical efficiency; whereas our troops at home are mainly composed of young and immature soldiers—boys, as they are termed—so that our camps and garrisons here are but feeding grounds for the supply of our battalions abroad. We may make up our minds to one thing—viz, that we must catch our recruits very young, or not at all, and be content to feed and drill them for some time before they can be of any use to us as soldiers. Once young men have already started in any calling in life, or are of an age to be thrown upon the labour market, the army is nowhere in

Digitized by Google

the competition. The questions that have, therefore, to be answered first of all is that of an increase of pay and advantages for the army. Some hold that the soldier should have, for example, a shilling a day clear, and be relieved of the system of stoppages, with all the unpopularity and discontent which that system entails, and that it would be better to alter the present system of deferred pay, which tempts men to leave the ranks in order to obtain a lump sum of money that is only squandered as soon as it is obtained. What is wanted is a system by which a larger number of young men of really good or promising physique may be tempted into the army at one end and retained in larger numbers at the other. The disposition in this country has always been to adopt and follow the particular system that has been successful in another country, without due regard to the tastes, habits, and requirements of our own population. Speaking generally, soldiering in India is popular when once the men have arrived there and become accustomed to the country, but the voyage out is often attended with extreme discomfort to many young men, who find themselves suffering from sea-sickness in a crowded ship. The European garrison of India has necessarily been much increased of late years, and India proves a great drain on the young manhood of the army owing to the diseases incidental to that climate and period of life. It is probable that the predisposition to typhoid fever in India is more attributable to the constitutional changes induced by recent arrival in that country than to any other factor, but with a short service system this is unavoidable. People, especially young people, in the present day are less amenable to control and discipline than their forefathers, and the calls made upon them in army life in this respect are looked upon as more irksome and distasteful than was formerly the case. Notwithstanding all the objections that have been urged against our present system, we do not see that a better or more economical one, capable of providing us with a large reserve, has yet been put forward.

THE PRODUCTION OF CHEMICALS BY ELECTRICITY.

CAUSTIC soda and carbonate of soda, next to sulphuric acid, are probably the most important industrial products of modern chemical manufacture. Neither occurs to any extent in nature, and the chemist accordingly resorts to that compound containing an abundance of the element sodium, which occurs as chloride in large quantities in sea water as well as in certain mines, notably those in Cheshire. Sodium chloride is converted by two well-known processes into the carbonate. The old system, discovered by a French *savant* named Leblanc, and known as the Leblanc process, depends upon the conversion of chloride into sulphate by treatment with sulphuric acid, and subsequent formation of carbonate by heating the resulting sulphate with coal and chalk. This method was threatened with extinction a few years back by the discovery of the ammonia process, which consists in the treatment of strong brine with ammonia and carbonic acid gas, by which bicarbonate of soda is formed and precipitated, while ammonium chloride enters into solution. Ammonia is recovered by heating with lime and the carbonic acid gas by heating the bicarbonate, which is thus converted into the normal salt Na_2CO_3. The by-products of the Leblanc process, amongst which are chlorine and sulphur, are, however, valuable. Electricity now promises to act as a successful agent in the production of valuable chemicals such as those indicated. On Wednesday last we inspected the electrolytic process for the direct production of caustic soda and chlorine, as well as other chemical products, at the works of the Caustic Soda and Chlorine Syndicate, Phœnix Wharf, Church-road, Battersea. It has of course long been well known that caustic soda and chlorine can be produced from a solution of common salt by electrolysis, but the many difficulties which have presented themselves have only recently been avoided by the adoption of special plant invented by Mr. J. Greenwood. Failure has hitherto resulted from the want of a material sufficiently refractory to resist the strong action of nascent chlorine. Mr. Greenwood uses a compound anode composed of non-porous carbon plates, separated by, but in contact with, a metal coil to increase their conductivity. The diaphragm, which is said to render the recombination of the electrolysed products impossible, is comparable to a Venetian shutter stuffed with asbestos. In commencing to work, the electrolytic vessels are charged with a solution of common salt, through which a current is then passed, thus decomposing or splitting up the salt into its elements, chlorine and sodium. In the preparation of sodium, however, a secondary action takes place, hydrogen is evolved, and the sodium is converted into caustic soda. The chlorine gas is conveyed by means of branch and main tubes into several absorbers, in which milk of lime, kept in a state of agitation, takes up the gas, and forms bleaching or chlorate liquor as may be required. The caustic soda is rendered more or less concentrated according to the particular purpose for which it is destined. The cost of production has, it is stated, been determined by carefully conducted electrical and analytical tests, and they are said to demonstrate an economy of over 50 per cent. as compared with present methods. The products obtained are, as might be expected, of especial purity, and the process promises to become a formidable rival to the two methods of the present day—the Leblanc and the Solvay ammonia method.

DEATH OF A FASTING MAN.

THAT the "fasting experiments" which have of late become so numerous are full of risk to the chief person concerned will not be disputed. An account is given in the *Boston Medical and Surgical Journal*, Nov. 26th, 1891, of a fatal attempt to fast for forty-five days. A man named George Stratton attempted to perform this feat. After going for thirty-seven days and one hour on water alone, his physicians ordered him two teaspoonfuls of champagne a day. At the end of forty-one days and eighteen hours and a half, however, symptoms of heart failure became so marked that it was at once decided to stop the fast. The champagne which was given him while in an extremely debilitated condition appeared to bring on alcoholism, and the next day he was transferred to a hospital. There he was treated with stimulants and peptonised food, but was unable to rally, and died two days after admission. The necropsy showed that death had resulted from cerebral congestion caused by alcohol, with fatty degeneration of the heart as a contributory cause. Stratton was a man thirty years old, and of immense physique. At the commencement of his fast he weighed 270¾ lb., and at the end 211 lb. 8½ oz., a loss of nearly 60 lb.

LECTURES AT THE ROYAL COLLEGE OF SURGEONS.

THE following are the arrangements for the various lectures at the Royal College of Surgeons of England for the present year, each lecture to commence at 4 P.M. Professor C. B. Plowright will give three lectures on "The Diseases of the Reproductive Organs of Plants caused by Fungi," on Feb. 22nd, 24th, and 26th. Professor B. T. Lowne, three lectures on "Some Recent Views on the Development of the Embryo, and the relation of the Parablast to the Blastoderm, as exemplified in the Development of Insects in the Egg and Pupa, on Feb. 29th and March 2nd and 4th. J. Hutchinson, Esq., jun. (Erasmus Wilson lecturer),

Digitized by Google

three lectures on "Syphilitic Affections of the Bones, Joints, and Lymphatic System," on March 7th, 9th, and 11th. Professor Charles Stewart, six lectures on "The Physiological Series of Comparative Anatomy in the Museum of the College," on 14th, 16th, 18th, 21st, 23rd, and 25th March. Dr. J. Rose Bradford (Arris and Gale lecturer), three lectures on "The Physiology of the Vaso-motor System," on May 23rd, 25th, and 27th. Professor C. W. M. Moullin, three lectures on "The Operative Treatment of Hypertrophy of the Prostate," on 30th May and June 1st and 3rd. Professor H. B. Robinson, three lectures on "Certain Diseases of the Breast," on June 7th, 8th, and 10th. Professor W. Watson Cheyne, three lectures on "The Treatment of Surgical Tubercular Diseases, on June 13th, 15th, and 17th. Professor H. T. Butlin, three lectures on "Cancer of the Scrotum in Chimney Sweeps and others," on June 20th, 22nd, and 24th.

"DOCTORS AND THEIR PAYMENT."

THE coroner for the district of Upton has either been misreported or has a peculiarly illogical way of reasoning on the work that is possible to a medical man. Holding an inquest on the body of George Day, who refused to see a doctor till within a few hours of his death, it transpired that Mr. Dodd had been sent for. As he could not go, he referred the messenger to his assistant, who could not attend. Three other doctors being unavailingly applied to, the messenger returned to Mr. Dodd, who went. The patient was by this time dead. Mr. Brickwell gave evidence of such extensive and chronic disease as precluded recovery under any circumstances. The coroner is reported to have made this remarkable observation, that if Mr. Dodd was able to attend on the second occasion, he was upon the first. This is a most gratuitous and illogical assumption for a public man to make, though it seems to have carried the jury with it. There was more common sense in his remark that doctors would be more prompt in their attendance if they had some security for eventual payment. The medical man is the only person who, according to common notions, is bound to be at everybody's beck and call without hope of fee or reward. There is no propriety in such doctrine.

THE LONDON LUNATIC ASYLUMS.

THE Asylums Committee of the London County Council have reported that for some time past they have had under consideration a letter from the Home Secretary, transmitting a copy of a memorial of the guardians of the Wandsworth and Clapham Union, praying that the London lunatic asylums should be placed under the Metropolitan Asylums Board, and asking for the Council's observations thereon. The memorial showed shortly as follows: "(*a*) That the memorialists are aggrieved at the vesting of the asylums in the London County Council, and submit that the duties of the Council are so enormous that it is impossible for them to efficiently administer the asylums; (*b*) that boards of guardians should be more in touch with the management of lunatic asylums than they are at present; (*c*) that many difficulties would be removed by placing them under the Metropolitan Asylums Board; (*d*) that there is no direct link between the boards of guardians and the London County Council; (*e*) that the Metropolitan Asylums Board have control of the imbecile asylums; (*f*) that Wandsworth Asylum was transferred to Middlesex, and 400 Wandsworth patients were sent to London and other asylums; (*g*) that their patients are distributed in asylums and licensed houses all over the country; (*h*) that the guardians have great difficulty in obtaining accommodation for recent cases, and that they consequently feel discouraged in their efforts to provide for the safety and comfort of lunatics belonging to their union; and, finally, (*i*) they pray that further legislation may be applied for to enable the suggestions of the memorialists to be carried out." The committee did not think that these grievances would be lessened by placing the lunatic asylums under the control of the Metropolitan Asylums Board, and they contended that the guardians appeared to lose sight of the fact that the county authorities have to deal with a large class of insane persons outside the range of the ordinary pauper; and that were their duties in this respect transferred to the Asylums Boards even greater inconveniences and hardships than these mentioned in the memorial might occur. We quite agree with the Council in their belief that it would be unwise to make changes in a system which could hardly be said as yet to have had a fair trial. They express their confidence that the system is working well, and they deliberately assert, and we think truly, that the lunatic asylums and their inmates receive as much thought, care, time, and personal supervision as they did under the management which prevailed before the Local Government Act. The committee do not think it advisable that lunatics as well as imbeciles should be placed under the control of the Metropolitan Asylums Board; but they believe that there would be advantage if eventually both classes were under one properly constituted authority. The committee, after dealing with some further points of detail in the question, recommended that a reply be sent by the clerk to the Home Secretary embodying their observations in the above sense on the memorial.

THE DETECTION OF ADULTERATION IN BUTTER.

AN instrument which is likely to be found useful in rapidly detecting adulterations in oils, glycerine, butter, &c., has recently been devised by a continental chemist named Soudén, under the name of the "liquoscope." It consists of a cylinder of glass containing glycerine, in which are immersed two hollow prisms side by side. When both these are filled with substances having identical refractive indices a horizontal line seen through them appears continuous, but when their contents have different refractive indices the line is apparently broken, one section being above the other.

TREATMENT OF CHLOROFORM ACCIDENTS.

IN an article in a Russian surgical review Prof. Bobroff recommends the employment of hypodermic injections of the physiological solution (0·6 per cent.) of common salt in case of failure of the heart's action during the administration of chloroform. He has employed this method for four years with satisfactory results, and considers it decidedly preferable to the subcutaneous injection of ether and other stimulants. With regard to ether, he says that it stimulates the cardiac action for a time only, afterwards having a paralysing effect. Strychnine, atropine, ammonia, the previous administration of digitalis, and the inhalation of amyl nitrite, he considers more or less dangerous and by no means satisfactory, while the hypodermic use of the physiological solution of common salt is perfectly innocuous, and has proved in his hands very valuable. It is best not to wait for complete stoppage of the heart or respiration. If only a moderate quantity of blood has been lost before symptoms of danger show themselves, an ounce or so of the fluid is sufficient to inject; in anæmic patients, or where a large quantity of blood has been lost, 3½ to 7 oz. may be required. The liquid is readily absorbed, especially if the locality is manipulated a little. The pulse becomes stronger, the respirations deeper, and the patient rapidly recovers. The solution may be made alkaline by the addition of

Digitized by Google

0·05 per cent. of caustic soda. Prof. Bobroff objects to the employment of such means of peripheral stimulation as affusion of cold water, the introduction of ice into the rectum, and putting ammonia to the nostrils, as these may by reflex action induce failure of the heart and arrest the respiration. The best and safest remedies are, he thinks, injection of solution of common salt hypodermically or into the venous circulation, lowering the patient's head, galvanising the pneumogastric nerve, and the employment of Silvester's method of artificial respiration.

THE RETIREMENT OF DR. BALLARD.

ALL Dr. Ballard's colleagues and all men who know the nature of the work he has been doing in the Medical Department of the Local Government Board will hear of his retirement with very mingled feelings. It has been known to his friends for some years that his health has been impaired, and that painful attacks of illness have repeatedly been brought on by the arduous journeys eagerly undertaken in the discharge of his duties. So far we may see in his retirement cause for satisfaction; but when we consider the value of his judgment in questions of State medicine and the number of the subjects in this department which he has elucidated, when we remember the enthusiasm of his investigations and the way in which he despised labour and trouble, we cannot but regret the loss which the department and the profession must suffer. It is gratifying, however, to know that Dr. Ballard's energy and interest in questions affecting the public health are still unabated, and that we may yet expect from him in his retirement contributions to the solution of great problems for which he had but scanty leisure while liable to the calls of active duty. We cannot conclude without expressing a hope that so good a servant will be retired on terms to which the possession of every virtue of character and of service entitles him.

NIGHT REFUGES AND THE "STARVING POOR."

CASES of death from absolute starvation are certainly less common than the frequent use of this term in the daily press reports would lead us to suppose. The association of disease is usually too subtle and too intimate for us to exclude its influence upon the fatal result. Inasmuch as this factor, however, exercises after all but a secondary influence, we need hardly object if want is made a scapegoat for the double fault. A few weeks ago we mentioned a case of this kind. We would now once more direct attention to such another in which the sufferer, an infant of eighteen months, though ill with congestion of the lungs, owed this and her death mainly to hunger and exposure. The case derives a special interest from the fact that while under investigation by Mr. Wynne Baxter and a coroner's jury it elicited some rather cutting observations on statements of the Charity Organisation Society respecting the homeless poor, and because of the light it sheds upon the utility, and we may say also upon the inadequacy, of night refuges. The point first mentioned need not be enlarged upon. The censures referred to have evidently arisen from a misunderstanding which the reply published by the secretary of the Society should suffice to remove. In connexion with the refuges, the food question is again to the front. The poor child whose case has been quoted was merely housed in the shelter frequented by her mother. No nourishment was provided. In the circumstances a question naturally arises whether the night refuge should not, as in the case of parish casual wards, afford its occupants at least food enough to sustain life. Our readers will reflect that a mere trifle of expense is enough to satisfy this primary necessity if a shelter be well attended and the simplest provision only be supplied. We should like to see the management of these shelters and the ordinary casual wards more nearly assimilated, so as to facilitate the attendance of every truly needy person, due care of course being taken to discourage imposture. How this latter purpose is to be realised, however, constitutes a problem still unsolved. The key to it may perhaps be found by combining inspection and, if possible, inquiry with some system of work which does not compel residence.

THE RATING OF THE LOCK HOSPITAL.

WE are glad to understand that the rating of the Lock Hospital, to which we referred on Aug. 1st last, has now been readjusted upon appeal. The case, as our readers will remember, was a peculiarly hard one, for not only was the assessment very greatly increased, but the managing body of the hospital were shut out from appealing in the regular course by the very irregular manner in which notice of the change was conveyed to them, the fact being that the statutory notice was given to a cleaner who chanced to be upon the hospital premises, and who forgot to hand it to any person in responsibility. It was at first apprehended that this oversight might preclude the appeal, but it now appears that this is not so. We were sanguine at the time that a technical objection of this kind could not be ridden so hard, and we are glad now to learn not only that the objection has broken down, but also that a substantial measure of justice has been done by the reduction of the assessment from £2000 to £1100.

HONORARY OFFICERS OF BENEFIT CLUBS AND MEDICAL ATTENDANCE.

DR. JOHN WILLIAM of Bethesda lately sued Mr. W. J. Parry, Collnor Hall, Bethesda, at the Bangor Police Court, for £65 for medical attendance. Various defences were set up. One that Mr. Parry, who is Vice-chairman of the Carnarvonshire County Council, and Chairman of the Joint Police Committee, was entitled to be attended as secretary, and therefore member, of the Penrhyn Quarries Benefit Club; another that the charge was partly on account of a son who is of age; and thirdly that the bulk of the debt was statute-barred. The judge, Sir Horatio Lloyd, decided that £42 8*s.* 6*d.* was statute-barred, that Mr. Parry was not entitled to be attended gratuitously inasmuch as he did not pay the weekly subscription demanded from ordinary members, but that he was not liable for the charges set against his son. Judgment was then given for £18 6*s*, his Honour declining to interfere with the question of costs further than signifying that the case was a fit one to be brought before the High Court, from which it had been transferred. The most interesting point is that a vice-chairman of a county council, who pays no weekly subscription to a club, claims to be attended as a club patient. We do not envy Mr. Parry his reflections on the non-success of such a monstrous plea.

MR. CHAMBERLAIN ON CRUELTY TO CHILDREN.

THE Birmingham Branch of the Society for the Prevention of Cruelty to Children was fortunate in securing an able exponent and advocate of its purposes at its annual meeting in the person of Mr. Joseph Chamberlain. Speaking of the necessity for the Society's operations, the right hon. gentleman had no difficulty in showing that the influence exercised by it in respect of legal evidence was of a kind as indispensable to the just restraint of cruelty as it was usually beyond the competence either of the police or of disinterested neighbours, however zealous and right minded. He drew special notice to another important fact—namely, that the prevention of cruelty, not the

Digitized by Google

punishment of ill usage, was the special aim of the Society's efforts; and in proof of this he quoted the satisfactory circumstance that of 8810 cases investigated 5064 had been satisfactorily disposed of by mere warning, while of the more aggravated class in which prosecutions had been instituted, the Society's officers had been victorious in 89 per cent. An assurance that no pains would be spared to maintain intact, wherever possible, the family tie was as satisfactory as it was happily needless. Reference was made likewise to the subject of infant insurance and of infant nursing by strangers, matters respecting which we are pleased to learn Mr. Chamberlain has not spoken his last word in Parliament. An exhortation to increased vigilance and care on the part of officials and local committees concluded an able and interesting speech, a fuller digest of which appears in the January number of the *Child's Guardian*.

SMALL-POX AT DEWSBURY AND BATLEY.

A VERY serious state of things has long been maintained at Dewsbury and Batley with regard to small-pox. Neither town will erect an isolation hospital, and whenever small-pox breaks out the patients, whether paupers or not, are sent to the Dewsbury workhouse and placed in a building within a few feet only of the workhouse infirmary, which contains people who, as the Government inspector has stated, are virtually prisoners by reason of their poverty and their sickness. On several occasions the small-pox has thus spread to the body of the workhouse; but in spite of remonstrances and warnings on the part of the Local Government Board the process was repeated last May. The disease spread to the infirmary sick, and three of these unfortunate people actually died as the result. Dr. Downes, Local Government inspector, again declared the arrangement to be "absolutely unsafe," and added that it placed the workhouse "in imminent peril"; but the guardians have again admitted eighteen cases "of small-pox, or 'so-called' small-pox." It is with the locality and the constituents of the authorities concerned that the judgment must apparently remain, for the erection of a hospital for infectious diseases is permissive, not compulsory, in the present state of the law. But surely the guardians could be surcharged for the expenses involved in maintaining those who are not paupers in a workhouse building which can only legally be used for pauper purposes.

THE OUTCRY AGAINST FOREIGNERS PRACTISING IN BELGIUM.

THE *Scalpel*, one of the chief organs of the Belgian medical press, is irate with the Government for the very insufficient protection it gives to native medical men against foreign competition. According to the journal mentioned, Belgium is, of all European countries, the one where foreign doctors, or *soi-disant* doctors, find it a perfectly simple matter to obtain a licence to practise. It is only necessary to produce a diploma with a translation by the candidate himself. Sometimes, indeed, in order to save appearances, a pretence of an examination is required, which is said to be a very perfunctory sort of affair, before a jury nominated for the occasion. The editor of the *Scalpel* has had the good fortune to be present at an examination of this kind, and he promises his readers to give them some account of it, as it amused him considerably. Who is it that profits by this liberalism? Not the English, French, or Dutch practitioners, "for in their own countries they can easily obtain a practice of from £400 to £800 per annum, besides which, as there are plenty of openings in their colonies, the profession cannot well become overcrowded" No, the doctors who come pressing into the best parts of Belgium, such as the neighbourhood of Antwerp and Ostend, are those that are forced at home to maintain a struggle against economic and social conditions more than usually adverse—e.g., the Germans. Their country is overrun with doctors of every kind of science, and every year, according to the statistics compiled by a Göttingen *savant*, Professor Lexis, the German universities turn out some three hundred more doctors than there is room for. The medical profession in Ostend, which is now suffering severely from foreign competition, is advised to bestir itself and to say to the Government, "You refuse to admit unsafe guns, poisonous spirits, and trichinous pigs from Germany. Why don't you send her back her starveling doctors?" Is not this a little hard on the Germans, who, whatever faults may be found with their ham and their cheap spirits, certainly produce men who are quite capable of passing the Brussels M.D. or other similar examinations, and who, as they probably practise mainly amongst their own countrymen, who abound at Ostend, can hardly be likened to the dangerous importations mentioned. In the list of requirements exacted from foreign medical men wishing to practise in various countries the *Scalpel* somewhat exaggerates the difficulties which a continental practitioner of good standing would meet with in England.

SIR WILLIAM DALBY.

SIR WILLIAM DALBY will have completed his term of twenty years as aural surgeon to St. George's Hospital at the end of this month. In sending in his resignation to the Medical School Committee he did not apply for re-election, on the grounds that he felt that he could not give the time necessary to attend efficiently to the out-patients. We understand that the Medical School Committee have written through their chairman to express their regret at losing his services, and have unanimously recommended the board of the hospital to elect him as consulting aural surgeon.

LEICESTER AND ITS FEVER HOSPITAL.

IT is satisfactory to find that Leicester is about to remedy its deficient accommodation for the treatment of typhoid fever, and to provide a new hospital in place of its present obsolete and unsatisfactory collection of wooden structures. The Town Council had before it for consideration on Tuesday last a proposal to erect a fever hospital with upwards of 200 beds upon the most modern and improved designs, where all or any of the infectious diseases can be properly treated and kept separate the one from the other. Premiums are offered of £100, £50, and £25 for the three best designs.

INTERNATIONAL DERMATOLOGICAL CONGRESS.

THE second International Congress of Dermatologists will take place at Vienna from Sept. 5th to the 10th, 1892. Professor Kaposi is president, and Dr. G. Riehl, Bellariastrasse, 12, secretary. The subjects chosen for discussion are: Lymphatic Disease of the Skin from a Pathological and Anatomical Standpoint; the Present Position of Leprosy in Europe; Dermatomycoses, and especially with reference to their proportion in France; Late Syphilis; the Anatomy and Development of the Epidermis Pigment; Psorospermosis; the Principles of the Treatment of Gonorrhœa; Lupus Erythematosus.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Montecot, the *doyen* of French physicians, at the age of ninety-eight. In 1813, when little over nineteen years

Digitized by Google

of age, he joined, in the capacity of surgeon-general, Lemarois' Corps, which then held Magdeburg, and, after the Battle of Leipzig, was shut up in the town until the end of the war. He was a Knight of the Legion of Honour, an Officer of Public Instruction, and was decorated with the Saint Helena Medal.—Dr. P. Laure of Lyons —Dr. Michelson, a teacher of laryngology in Königsberg.

FOREIGN UNIVERSITY INTELLIGENCE.

Greifswald.—Dr. E. Peiper has been promoted to an Extraordinary Professorship of Medicine.

Marburg.—Dr. Tuczek has been promoted to an Extraordinary Professorship of Mental Diseases.

Naples.—Drs. Manfredi and Lancetti have been recognised as *privat docenten* of Hygiene and Anatomy respectively.

WE have received from an Edinburgh correspondent an abstract (which we hope to publish and comment upon in our next issue) of an important document which has been prepared by the Edinburgh Association for the Promotion of Reform in Medical Education.

As we go to press we receive with regret the intelligence of the death of Mr. Berkeley Hill, Vice-president of the Royal College of Surgeons, Professor of Clinical Surgery at University College, and surgeon to the hospital.

DR. FREDERIC KORANYI, Professor of Medicine at the University of Budapest, was raised on New Year's Day to the House of Magnates of Hungary.

LONDON POST-GRADUATE COURSE.

THE annual general meeting was held on Thursday, Dec. 17th, 1891, at 15, Cavendish-square, Mr. Hutchinson, F.R.S., President, in the chair.

After the minutes of the last meeting had been read and confirmed, Dr. Barker, the chairman of committee, read the financial report, from which it appeared that during the spring term 1890, when the lectures commenced, there were five courses delivered, and that during the spring term 1892 there will be eleven courses delivered at the following hospitals and institutions—viz., the Hospital for Consumption, Brompton; the Hospital for Sick Children, Great Ormond-street; the National Hospital for the Paralysed and the Epileptic, Queen-square; the Royal London Ophthalmic Hospital, Moorfields; the Hospital for Diseases of the Skin, Blackfriars; Bethlem Royal Hospital for Lunatics; the London Throat Hospital; the Bacteriological Laboratory, King's College; the Great Northern Central Hospital; the Parkes Museum; and a course on midwifery and diseases of women by lectures on these subjects at the London Medical Schools. During 1891 there had been 172 entries (160 men and 12 women). Of these, 108 were from the British Isles, 13 from the United States, 9 from Canada, 9 from the Army, 8 from the Navy, 6 from Australia, and 1 each from Sweden, the Cape, the Mauritius, New Zealand, Assam, China, and Japan. The widespread interest in the work affords great encouragement, and it is worthy of notice that whilst the bulk of the members are from our own country, men have joined who have come from the remotest parts of the world. It is also gratifying to remark that so many of the men possess high qualifications, more than one-half holding university degrees. The English, Irish, and Scotch Universities were well represented, as well as those of the Colonies and the United States. The bacteriological course conducted by Professor Crookshank in the excellent laboratory of King's College formed undoubtedly the great attraction of the courses, and was an admirable illustration of the objective method of class teaching. This course throughout was well attended. Judging from the number of inquiries, the course on Public Health and that on Midwifery and Diseases of Women will be equally successful. The treasurer, Dr. C. Theodore Williams, then read his report and presented the balance-sheet and scheme for division of fees. From these it appeared that the receipts exceeded those for the previous year, whilst the expenses had been reduced. There were 172 attending the lectures, as compared with 121 in 1890. Twenty members entered for the whole course, and 152 for one or more of the single courses. It had been interesting to observe how the men had picked out those lectures that enabled them to fill up the gaps in their previous studies. The president, Mr. Hutchinson, then addressed the meeting, and, after other speakers had discussed the reports, they were unanimously adopted. Votes of thanks were passed to the president, chairman, treasurer, and secretary, and they were re-elected for the ensuing year.

The next term will commence on Monday, Jan. 18th, and all information may be procured from the secretary, Dr. J. Fletcher Little, 60, Welbeck-street, London, W.

ROYAL COLLEGE OF PHYSICIANS.

AT an extraordinary meeting of the Royal College of Physicians, held on Dec. 17th, 1891, a communication was received on the subject of the resolution of the General Medical Council, which was moved by Sir William Turner on Friday, Nov. 27th, by which the Council determined to leave that College to substantiate the claim to register its single diploma of Licentiate or Member as a completo qualification in medicine, surgery, and midwifery.

With regard to this resolution, the College approved the course which had been taken by its officers in submitting the question for their opinion and advice to the law officers of the College, the Attorney-General, with Sir Arthur Watson, Bart., Q.C. The question raised by the College for the opinion of counsel was—(1) Are they correct in the view they take of the right of their licentiates to claim registration of their licence as a complete and independent qualification? The counsel's opinion thereon is as follows:

(1) We are of opinion that the College are correct in the view they take of the right of their licentiates to claim registration of their licence as a complete and independent qualification. (Signed) RICHARD E. WEBSTER, ARTHUR T. WATSON.

Dec. 18th, 1891.

THE ALBERT UNIVERSITY CHARTER.

WE have received from the Secretary of the Association of Diplomates and Students of the London Medical Schools a copy of the circular which, we are informed, is intended to be sent to all the diplomates of London schools along with a petition which is to be presented to the House of Commons. The petition runs as follows:—

TO THE HONOURABLE THE COMMONS OF THE UNITED KINGDOM OF GREAT BRITAIN AND IRELAND IN PARLIAMENT ASSEMBLED.

The Humble Petition of the Students and Diplomates of and in the London Medical Schools

Sheweth as follows (that is to say):—

The draft of a proposed Charter, called the Draft Charter of the Albert University, hereinafter called "the Proposed Charter," has been laid upon the table of your honourable House pursuant to the provisions of an Act of Parliament made and passed in the Session of Parliament holden in the 34th and 35th years of the reign of Her present Majesty, Queen Victoria, intituled an "Act to amend the law respecting the granting of charters in certain cases," and thereby authorised to be cited as "The College Charters Act, 1871."

Your petitioners will be injuriously affected by the granting of a Charter in the form in which the proposed Charter now stands, and they desire the amendment thereof for the reasons and in the manner hereinafter appearing. Clause 1 of the "proposed Charter" provides (*inter alia*) as follows: "There shall be, and there is hereby constituted and founded, a University in and for London, with the name of the Albert University" (which University is hereinafter referred to as "the proposed University"). Clause 2 of the "proposed Charter" provides as follows: "University College, London, and King's College, London, shall be and are hereby constituted Colleges of all Faculties in the University. The following medical schools shall be and are hereby constituted Colleges of Medicine in the University: The Charing-cross Hospital Medical School, the Guy's Hospital Medical School, the London Hospital Medical School, the Middlesex Hospital Medical School, the St. Bartholomew's Hospital and College Medical School, the St. George's Hospital Medical School, the St. Mary's Hospital Medical School, the St. Thomas's Hospital Medical School, the Westminster Hospital Medical School, and the London School of Medicine for Women. Clause 3 of the "proposed Charter" provides as follows:—"The University shall have power to confer degrees in the Faculties of

Digitized by Google

Arts, Science, Law, and Medicine, and in such other Faculties corresponding to the provinces of study and educational work occupied by the University on all persons, male or female, who shall have pursued a regular course of study in a college in the University, and shall submit themselves for examination."

Your petitioners are, or have been, students of the colleges and schools named in Clause 2 of the proposed Charter, or of some or one of them. And they humbly submit that according to the text of the last-mentioned clause of the proposed Charter it will only be open to students who, after the proposed University becomes incorporated, shall undergo a course of two years' study in one of the medical schools proposed to be made colleges in "the proposed University to take the degrees, which by virtue of the proposed Charter the Council of the proposed University would be empowered to grant.

Your petitioners submit that this restriction is unjust to them and to other students and diplomates of the London medical schools who are passing or have passed through the exact course of studies and the same examinations as the future student will have to pass, inasmuch as they will be debarred from presenting themselves for examination for the purpose of taking the degrees of the proposed University unless they again attend for two years a college in the proposed University.

Your petitioners therefore submit that Clause 3 of the proposed Charter should be made retrospective, and should be altered and amended as shown in the copy of that clause next hereinafter set forth (that is to say):—"The University shall have power to confer degrees in the Faculties of Art, Science, Law, and Medicine, and in such other Faculties corresponding to the provinces of study and educational work occupied by the University on all persons, male or female, who shall have pursued, whether before or after the coming into operation of the Charter," a regular course of study in a college in the University "or in any Institution which is hereby constituted a College of the said University," and shall submit themselves for examination.

Your petitioners therefore humbly pray your honourable House that it will be pleased to present an address to Her Majesty praying Her Majesty to withhold her consent to such part of the proposed Charter as is contained in Clause 3 thereof until the same is amended as hereinbefore set forth, or to the like effect. And your petitioners will ever pray, &c.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6751 births and 6572 deaths were registered during the week ending Jan. 2nd. The annual rate of mortality in these towns, which had been 19·1 and 22·8 per 1000 in the preceding two weeks, further rose to 36·4 last week, a higher rate than in any week since 1880. Some of this large excess is due to the delay in registration caused by the Christmas holidays during the preceding week, but it is mainly attributable to the cold and foggy weather that recently prevailed. The rate was as high as 42·0 in London and 31·9 in the twenty-seven provincial towns. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the twenty-eight towns averaged 21·2 per 1000, and was 0·5 below the mean rate in the corresponding periods of the ten years 1881–90. The lowest rates in these towns last week were 19·4 in Halifax, 20·5 in Leicester, 21·8 in Huddersfield, and 22·0 in Birkenhead; the highest rates were 37·0 in Newcastle-upon-Tyne, 38·3 in Brighton, 42·0 in London, 42·2 in Liverpool, and 45·3 in Wolverhampton. The deaths referred to the principal zymotic diseases, which had been 395 and 461 in the preceding two weeks, further rose last week to 667; they included 273 from whooping-cough, 224 from measles, 52 from diarrhœa, 48 from diphtheria, 36 from scarlet fever, 34 from "fever" (principally enteric), and not one from small-pox. No fatal case of any of these diseases was registered in Brighton; in the other towns the lowest zymotic death-rates were recorded in Huddersfield, Plymouth, and Halifax, and the highest in Blackburn, Wolverhampton, London, and Cardiff. The greatest mortality from measles occurred in Birmingham, Nottingham, Derby, Newcastle-upon-Tyne, Norwich, and Cardiff; from whooping-cough in Bradford, Oldham, Cardiff, London, Derby, Blackburn, and Wolverhampton, and from "fever" in Norwich. The mortality from scarlet fever showed no marked excess in any of the twenty-eight towns. The 48 deaths from diphtheria included 37 in London and 3 in Manchester. No fatal case of small-pox was registered in any of the twenty-eight large towns; three small-pox patients were under treatment on Saturday last in the Metropolitan Asylum Hospital at Dartford, but not one in the Highgate Small-pox Hospital. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1471, against numbers declining from 1554 to 1465 at the end of the preceding four weeks; 101 new cases were admitted during the week, against 109 and 90 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 337 and 553 in the preceding two weeks, further rose last week to 1317, and were considerably more than double the corrected average. The causes of 163, or 2·5 per cent., of the deaths in the twenty-eight towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Wolverhampton, Derby, Birkenhead, Bolton, and Oldham; the largest proportions of uncertified deaths were registered in Liverpool, Blackburn, Sheffield, and Birmingham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 26·0 and 27·1 per 1000 in the preceding two weeks, declined again to 26·0 during the week ending Jan. 2nd, and was 10·4 below the mean rate during the same period in the twenty-eight large English towns. The rates in the eight Scotch towns ranged from 15·6 in Paisley and 18·6 in Perth to 28·9 in Aberdeen and 29·3 in Glasgow. The 670 deaths in these towns showed a decline of 28 from the number in the preceding week, and included 22 which were referred to whooping-cough, 11 to diphtheria, 11 to diarrhœa, 10 to "fever," 9 to scarlet fever, 6 to measles, and not one to small-pox. In all, 69 deaths resulted from these principal zymotic diseases, against 50 and 41 in the preceding two weeks. These 69 deaths were equal to an annual rate of 2·7 per 1000, which was 1·0 below the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 12 and 16 in the preceding two weeks, further rose to 22 last week, of which 15 occurred in Glasgow and 3 in Aberdeen. The deaths referred to diphtheria, which had been 4 in each of the previous two weeks, increased to 11 last week, and included 4 in Glasgow, 3 in Edinburgh, and 2 in Aberdeen. The 10 fatal cases of "fever" exceeded those recorded in any recent week, and included 5 in Glasgow. The deaths from scarlet fever, which had been 11 and 4 in the preceding two weeks, rose to 9 last week, and included 3 in Glasgow, 3 in Greenock, and 2 in Edinburgh. Of the 6 fatal cases of measles, 5 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 246 and 254 in the preceding two weeks, declined last week to 203, but slightly exceeded the number in the corresponding week of last year. The causes of 67, or 10 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 33·9 and 29·1 per 1000 in the preceding two weeks, rose again to 45·8 during the week ending Jan. 2nd. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 29·8 per 1000, against 20·5 in London and 25·5 in Edinburgh. The 305 deaths in Dublin during the week under notice showed an increase of 111 upon the number in the previous week, and included 10 which were referred to different forms of "fever," 8 to whooping-cough, 2 to diarrhœa, 1 to diphtheria, and not one either to small-pox, measles, or scarlet fever. In all, 21 deaths resulted from these principal zymotic diseases, equal to an annual rate of 3·2 per 1000, the rate during the same period being 5·2 in London and 2·0 in Edinburgh. The fatal cases of "fever," which had been 7 and 9 in the previous two weeks, further rose to 10 last week. The deaths referred to whooping-cough, which had steadily risen in the preceding four weeks from 2 to 5, further increased to 8 last week. The 2 fatal cases of diarrhœa corresponded with the number in the previous week. The 305 deaths registered in Dublin included 37 of infants under one year of age, and 113 of persons aged upwards of sixty years; the deaths of infants differed but slightly from the average, while those of elderly persons considerably exceeded those recorded in any week of 1890. Twelve inquest cases and 9 deaths from violence were registered; and 118, or more than a third, of the deaths occurred in public institutions. The causes of 19, or more than 6 per cent., of the deaths in the city were not certified.

MORTALITY IN QUEENSLAND.

It appears from the report recently issued by the Registrar-General of Queensland that the rate of mortality in

Digitized by Google

that colony in 1890 was considerably lower than in any recent year. The death-rate in 1890 was 13·6 per 1000, against rates ranging in the nine preceding years from 23·0 in 1884 to 14·6 in 1887. It should be stated that these rates appear to have been based upon population for each year of the intercensal years 1881 to 1890, estimated from the excess of births over deaths, and from the excess of immigration over emigration, without regard to the results of the census in April last. From a comparative table given in the report under notice it is shown that the death-rate in 1890 in the several Australian colonies ranged from 9·6 and 12·0 per 1000 in New Zealand and Western Australia, to 13·8 in Tasmania and 15·9 in Victoria. All these rates are remarkably low; and bearing in mind the difficulties in the way of death registration in very thinly populated districts, it is very possible that the true death-rates are somewhat under-stated in most of these colonies. There is no satisfactory basis for estimating the varying extent of this under-statement in the several colonies. With regard to the Queensland statistics, it is interesting to note that the deaths in 1890 included 89 of Chinese, 450 of Polynesians, and 16 of other alien races. Calculated upon the estimated number of persons living of each race, the rate of mortality was equal to 12·3 per 1000 among the Chinese, 46·4 among the Polynesians, and 10·3 among persons of other alien races. It must be remembered that these rates among aliens, mainly imported labourers, are the rates among persons in the prime of life, and in a certain sense selected lives. This fact accentuates the enormity of the excess in the death-rate among the Polynesian labourers imported from the South Sea Islands. With reference to this subject the Registrar-General of Queensland remarks: "The in-breeding for long periods of certain tribes in the islands produces a race who seem extremely liable to contract phthisis, so that the change of climate from the humid atmosphere prevailing in the islands of the South Seas to the drier air of this continent and the great difference of diet &c., all tend to predispose a naturally weak constitution to a disease most fatal amongst them." Does this explanation supply any facts to weaken the grave responsibility of the colonial authority which sanctions this imported labour system in the face of so terrible a loss of life? We would also notice that the Queensland Registrar-General, in pointing out that the death-rate among the Chinese is lower than that of the European races, omits to notice that the two populations have very different age proportions, and that, corrected for this difference, the Chinese rate shows a very considerable excess.

THE SERVICES.

ARMY MEDICAL RESERVE.

A new Royal Warrant has been issued from the War Office, which directs that in the Army Medical Reserve of Officers the new designations of Surgeon-Lieutenant-Colonel, Surgeon-Major, Surgeon-Captain, and Surgeon-Lieutenant shall be substituted for the ranks hitherto borne. It is further ordered that promotion shall take place on completion of the periods of service required according to ranks in the Militia, Yeomanry, and Volunteers, except that promotion to Surgeon-Major shall be given on completion of twelve years from the first appointment. Honorary Assistant Surgeons permitted to join the Reserve will be given the rank of Surgeon-Lieutenant.

NAVAL MEDICAL SERVICE.—The Greenwich Hospital pension of £50 a year, vacant by the death of Deputy Inspector-General of Hospitals and Fleets Andrew Murray, has been awarded to Deputy Inspector-General of Hospitals and Fleets W. H. Adam.—The following appointment has been made at the Admiralty:—Staff Surgeon Thomas E. H. Williams to the *Impregnable* (dated Jan. 2nd, 1892).

IMPROVED BURIAL LEGISLATION.—A conference was held on the 3rd inst., in the vestry of St. Edmund, King and Martyr, London, "to consider the desirability of improved burial legislation and the appointment of a Minister of Health." Archdeacon Sinclair of London presided. The subject was well discussed and a resolution adopted to memorialise Lord Salisbury, suggesting the necessity of a change with regard to burials and the need of fresh legislation on the question.

Correspondence.

"Audi alteram partem."

MEDICAL DEFENCE UNION.

To the Editors of THE LANCET.

SIRS,—Dr. Hugh Woods' criticism of the proposed alterations in the Articles of Association of the Medical Defence Union have already been fully and, I trust, satisfactorily answered both by Dr. Leslie Phillips and myself in the columns of your contemporary, the *British Medical Journal*. As, however, there may be many of your readers who are not members of the Association, and do not therefore read the journal, I must claim your indulgence, and ask you to permit me to give a *résumé* of the reasons which compelled us to advocate the alterations referred to by Dr. Woods. After three years' working it was found that certain of the by-laws were distinctly adverse to the future prosperity of the company. One of these, against the wishes of the executive, on whom the sole legal responsibility of the correct working of the Union lies, was used at the last annual meeting to work a semi-political agitation against the Midwives' Registration Bill.

Whilst not expressing any opinion for or against such a Bill, the directors felt that to use the Union's funds—which are small enough, in all conscience, and are required for the defence of the individual member against false charges—for such a purpose was adverse to the interests of the company, although, legally speaking, "within its rights." At the earliest possible opportunity, therefore, after the general meeting a subcommittee was appointed, and, aided by the solicitors, certain alterations were suggested which were considered advantageous. The repeal of the by-law permitting the funds of the Union to be used for public agitations was decided upon. If every medical man subscribed to the company no exception could be taken to the carrying out of any agitation for the benefit of the profession as a whole; but as such is not the case, the directors, in my opinion, decided wisely in wishing to husband their funds for the furtherance of the *raison d'être* of the company—viz., individual defence of the member or subscriber.

I do not believe for one moment that Dr. Woods' opinion, as expressed in his letter, will be shared by any member who will look carefully into the matter. Again, with regard to the election of the directorate. Here we follow in our proposed new laws the rules of every limited company in the United Kingdom. Instead of the whole body of directors being liable to be rejected at an annual meeting by a catch vote, we suggest that a certain number shall retire annually, so as to give a sensible infusion of new blood, but at the same time to prevent the chaos which would arise were the whole body to consist of new members, to whom the work would be unknown. The present directors have done wonders in raising the Union from such a "slough of despond" in which they found it. Dr. Leslie Phillips' work has been extremely arduous; thousands of letters are written each year by him, and each day's duties occupy some hours on behalf of the Union. All these duties cannot be learned at once, and our duty as sensible men is to retain the valued services of such men as the present directors as long as they will continue to give their time and care to the Union. The Union was wrecked before by want of such care and attention. Let us now be thankful that it is prospering, and likely to continue prospering as long as we realise that our aim is the defence of the individual member. The Parliamentary Bills Committee and the General Practitioners' Union are both at the service of those who wish to agitate for various items in medical reform. As an insurance society, our company has no right to interfere in such matters, and it is by upholding this contention that we have reaped our present success, although at the cost of adverse criticism from Dr. Hugh Woods. I trust, however, that by patience we may be able to win finally this gentleman's applause.

I remain, Sirs, yours faithfully,

A. GEORGE BATEMAN, M.B.

Longridge-road, S.W., Jan. 6th, 1892.

ANTISEPTICS IN OPHTHALMIC SURGERY.

To the Editors of THE LANCET.

SIRS,—I regret that my letter in THE LANCET of Dec. 19th was not sufficiently explicit to convey my meaning to your correspondent, Dr. Johnson Taylor. If Dr. Taylor will refer to Dubief's paper he will see that the presence of organisms in the lens after extraction was demonstrated by cultivation in sterilised broth and not by the microscope. I experimented on the rabbit's eye in order to test Dubief's results for my own satisfaction. In both experiments the object was to test the efficacy of antiseptics—that is, their power of destroying germs; and the fact which Dr. Taylor puts forward as rendering my experiment futile—namely, that I was dealing with dead matter "absolutely devoid of resisting power" towards germs—was an essential condition both in Dubief's and my own experiments. It is obviously impossible to test the efficacy of an antiseptic in protecting from germs a substance which itself possesses antiseptic power. In my letter I pointed out that we can only test an antiseptic method by experimenting in such a way that, if it fails to destroy all germs, those that escape must infallibly show their presence. I quite agree with Dr. Taylor that the living tissues possess antiseptic properties—the fact cannot be doubted; and I said that the fact of a wound doing well is no evidence that germs have been excluded from it.

Dr. Taylor admits that antiseptics do not kill germs, and that the majority of successful results are due to the power of the tissues to resist infection; but he makes the suggestion that antiseptics may so far weaken the germs as to be of service in cases in which the tissues possess only a small resisting power. Now, this is precisely the question which it is interesting to solve. *A priori* arguments will not help us. We know that in sufficient strength antiseptics kill not only the germs but the tissues, and it is a nice question to decide which of the two would die first. The supposition that antiseptics weaken the germs and enable the tissues to finish them, does not, as far as I know, rest on any better basis than the opposite supposition that the tissues may be rendered weaker and the germs enabled to destroy them. This question can only be decided by a comparison of the results obtained with and without antiseptics. Dr. Taylor thinks that the records of metropolitan ophthalmic hospitals show better results with antiseptics than without them. I shall be extremely obliged to him if he will kindly inform me what the data are which led him to this conclusion. He will of course bear in mind that to say "before and after the introduction of antiseptics" is very different from saying "with or without the use of antiseptics." Finally, Dr. Taylor begs the whole question by comparing antiseptics to a *reliable* life-belt. The *reliability* is the point at issue. A straw life-belt has been found a useless encumbrance. Antiseptics may also be worse than useless; and, as I said before, the time has arrived when it is desirable to decide this question by a comparison of the results of a large number of operations, antiseptic and otherwise. I suggest that the best way to make this comparison, and to eliminate the element of personal dexterity, which is irrelevant to the question, would be for an equal number of surgeons who use and who do not use antiseptics in cataract extraction to send you the results of 100 consecutive cases—not for publication, but to be compared and impartially reported upon by the Editors of THE LANCET.

I am, Sirs, yours faithfully,

Southampton, Jan. 4th, 1892. J. F. BULLAR.

THE ELECTRO-MAGNET AND FOREIGN BODIES IN THE RETINA.

To the Editors of THE LANCET.

SIRS,—In recording a case of removal of a piece of steel from the retina, which appeared in your issue of Oct. 24th, I did not attempt to enter into the question of the treatment of foreign bodies in the fundus generally. I merely recorded a rare case, and quoted the only successful cases which, so far as I was aware, had been previously recorded. In a subsequent number Dr. Neale wrote pointing out that I had omitted to quote cases of Mr. Snell's. I wrote to Mr. Snell to ask if that was so, and he, in reply, referred me to his series of electro-magnet cases and to the Ophthalmological Society's Transactions for 1886. Not having in my possession or available that volume of the Transactions, I relied on a search through the series I understood I was referred to, and there found the three cases I mentioned in my last letter under the head of "Retina," and the other case I quoted under the head of "Retina-vitreous." The electro-magnet was used in each of the first three cases, but without result as far as removal of the foreign body was concerned; but I may have given a wrong impression in speaking of them as cases in which unsuccessful attempts were made to remove foreign bodies from the retina, seeing that no absolute diagnosis of their presence there was made beforehand. Their being recorded under the heading of "Retina" misled me. I now find that Mr. Snell's case of successful removal was not included in the series; and having obtained the volume of the Transactions referred to, I have read his case with interest, and wish to express my apologies to Mr. Snell and my assurance that the oversight of this case was quite unintentional. I agree with Mr. Snell's remarks about the possible danger of needlessly attempting the removal of foreign bodies in the retina, having myself come across two cases in which a foreign body had remained so situated for several years without materially disturbing visual function.

I am, Sirs, yours faithfully,

Cardiff, Jan. 5th, 1892. J. TATHAM THOMPSON.

MR. A. E. BARKER'S FIFTY CONSECUTIVE CASES OF AMPUTATIONS OF THE LIMBS.

To the Editors of THE LANCET.

SIRS,—As a practical surgeon I congratulate Mr. A. E. Barker upon the success which he has obtained in his fifty cases of limb amputation; but the importance of the report is marred by the absence of any information as to the ages of the forty-six patients who recovered. This omission is unfortunate, as the age is one of the factors which tells largely either for or against a successful or an unsuccessful operation, and unless the information in this direction is supplied the usefulness of Mr. Barker's statistics for the purpose of comparison will be minimised, if not destroyed.

I am, Sirs, yours truly,

Wolverhampton, Jan. 2nd, 1892. T. VINCENT JACKSON.

THE INTERNATIONAL SANITARY CONFERENCE AT VENICE.

(FROM OUR ITALIAN CORRESPONDENT.)

ON Dec. 12th THE LANCET announced that a Conference would meet at Venice on Jan. 5th to consider the "re-organisation of the Sanitary Commission of Alexandria, and the conditions under which vessels in quarantine may pass through the Suez Canal." The preparations for this important Conference are now, I may say, complete; Germany having just nominated as her representatives at the same Count Leyden, Consul-General at Cairo, and Dr. Kulp of Alexandria. By arrangement of the Venetian Town Council the sittings will take place in the Palazzo Farsetti, and during the six days these will occupy every disposition will be made for the convenience and recreation of the delegates. The Piazza di San Marco will be illuminated on the evening of the 5th, a "serata di gala" will be given at the Fenice theatre on the 6th, and the Commendatore Colmayer, the prefect, will hold a reception in honour of the representatives of the Powers at Ca' Corner on the 11th. So far nothing will be wanting to promote the success of the Conference; but there are already indications that its proceedings will, to say the least, be animated. French anglophobia will, it is feared, find matter distinctly contentious in the proposal to dispense English vessels from sanitary inspection in the Suez Canal, and its organs in the press are already calling on the Austro-Hungarian and German delegates to resist the "pretensions" of England in the interests of the "general hygiene of Europe." The old prejudices in favour of quarantine, which, it will be remembered, made shipwreck of the Conference that met with a similar object in Rome in the May of 1885, will be pressed once more into service—ostensibly to "protect the general hygiene of Europe," really to combat what France absurdly contends is the policy of England: that of making the "Red Sea an English lake." There are signs, however,

Digitized by Google

that France will have less support for her anglophobia than she counts upon. In the first place, quarantine has been sufficiently discredited—by none more than Tommasi-Crudeli—since the Rome conference to make it a very doubtful weapon of obstruction before such an international tribunal as that which meets on the 5th. In the next place, France may count upon receiving as little aid from Italy as she is likely to do from Austria-Hungary or Germany. A good deal has happened since 1885; and as evidence of what is likely to be the attitude of Italy towards England at the approaching conference, I may quote the opinion of a high-placed Italian publicist. "The instructions," he says, "received by our delegates are strictly reserved and not to be divulged. But from the demeanour of France in Egypt, smarting as she is under the loss of her influence there, and bent on always creating obstacles for *la perfide Albion*, and, on the other hand, from the cordial relations we enjoy with the 'Cabinet of St. James,' we may anticipate perfect harmony of views between England's delegates and our own." Italy, as already announced in THE LANCET, will be represented by his Excellency Signor D'Arco, Under-Secretary of State for Foreign Affairs, who will have as his assistant that skilled diplomatist the Marchese Silvio Carcano, Consul-General of Italy in Egypt, who as resident minister in Chili asserted Italian interests in South America with equal ability, firmness, and tact. Another Italian representative will be Professor Pagliani, Director of State Medicine in the kingdom of Italy, and yet another will be Dr. Andrea Torella, sanitary delegate in Egypt, and intimately acquainted with the hygiene of that country, especially in Red Sea waters. These men, according to the Italian publicist just referred to, are much more in unison with English than with French views of international sanitation, and will, he expects, receive from the enlightened delegates of Germany and Austria-Hungary a support for the reformed sanitary regulation of Red Sea traffic which will more than outweigh the *vis inertiæ* of the Porte or the obstructive tactics of France.

A list of the statesmen and hygienists who represent the Powers at this conference has just been officially given by the organ of the Italian Government, and in the following order:—England: Mr. J. W. Lowther, Under-Secretary of State for Foreign Affairs, and Dr. Mackie, English delegate to the Sanitary Council of Alexandria. France: M. Camille Barrère, chargé d'affaires at Munich, and Professors Brouardel and Proust, the former President of the French Sanitary Council, and the latter Inspector-General of the Sanitary Service of France. Austria-Hungary: Geheim-Rath Count Karl Küfstein, Herr C. von Csiller, ex-Consul in Egypt, now delegate to the Danube Commission and Consul-General at Galatz, and Dr. von Nagel, Austro-Hungarian, delegate to the Sanitary Council of Constantinople. Germany: Count Leyden, Consul-General at Cairo, and Dr. Kulp, delegate to the Sanitary Council of Alexandria. Russia: The Privy Councillor Jomini. Spain: The Resident Minister, De Bagner, and Dr. Maria Cortezo. The Netherlands: Dr. Jonkheer-van-de-Does-de-Willebois, Consul General at Cairo, and Dr. Ruysch, Sanitary Councillor to the Minister of the Interior. Belgium: M. E. Beco, Secretary-General to the Ministry of Agriculture, Industry, and Public Works. Denmark: Count Knuth, Minister at the Court of the Quirinal. Egypt: Butros Pasha, Under-Secretary of State to the Minister of Justice, M. Mieville, President of the Sanitary Council at Alexandria, and Mahmend Pasha, vice-Director of the Internal Sanitary Service. Greece: by her diplomatic representative at Rome and by her delegate to the International Sanitary Commission at Alexandria. Turkey: by four delegates (names not yet announced); and Italy: Count d'Arco, Under-Secretary of State for Foreign Affairs; the Commendatore Pagliani, Director of the Sanitary Office in the Ministry of the Interior; and the Commendatore Carcano, Consul-General in Egypt.

January 2nd.

FRENCH OPINION ON QUARANTINE.

(FROM OUR SPECIAL CORRESPONDENT.)

THE meeting of the International Conference at Venice to discuss the question of quarantine renders it interesting to study the views entertained abroad on this subject. M. Henri Monod, who is Director of the Public Hygiene Department at the Ministry of the Interior, represents the most enlightened French views on the subject. M. Monod has an excellent knowledge of English, and his recent publication on the progress of sanitary reform in England proves that he thoroughly appreciates what has been achieved in this country. Under these circumstances I availed myself of M. Monod's invitation to call and talk the matter over with him. M. Monod lives in the English style—that is, not in an apartment or flat, but in a villa that stands by itself. His library is full of English publications, notably all the Local Government Board Blue Books relating to public health, the Registrar-General's returns &c., which he estimates so highly that he has had them preserved in artistic bindings. His conversation showed that these works had not rested idly in his library, but had been carefully studied. It was also very soon evident that very considerable misunderstanding prevails as to the views which in England it is supposed the French entertain with regard to quarantine and the transmission of cholera. M. Monod again and again protested that he did not believe there was any difference of opinion between Dr. Buchanan, Dr. Thorne Thorne, and himself. M. Monod recognises that by the adoption of sanitary measures, rather than by the enforcing of quarantine, epidemics can best be averted; but he insists that England, like other countries, sought to protect herself by quarantine till such time as her great sanitary works are completed. Quarantine was maintained in 1866, for Sir John Simon protested against it, and urged that it had not prevented the 14,000 deaths from cholera. It was only in 1884 that England was again seriously menaced by cholera, and by that time such great progress was accomplished in sanitation that England could afford to dispense with quarantine. If, he said, the English expect such unhealthy, badly drained ports as Marseilles, Toulon, Constantinople, &c., to dispense with quarantine, then they expect foreign countries to do what England herself did not do.

M. Monod argues that English medical men recognise that cholera is endemic in India, that it can be transmitted, notably by soiled linen brought from India in a ship. It does not matter whether such a ship be English or foreign; the fact that soiled linen is on board an English ship does not make it less infectious. Of course I was obliged to recognise that the English flag did not possess any special antiseptic properties, and M. Monod reminded me that in 1832 the cholera came to France from England, the epidemic commencing at Calais. Then again in 1865 an English ship, the *Sidney*, brought the cholera to Egypt, whence it spread in Europe. England by its geographical position enjoys a natural quarantine—namely, the time vessels take to reach its shores. But the English Crown Colonies of Cyprus, Malta, and Gibraltar, which are in the same position as the Mediterranean Powers, impose quarantine regulations of even greater severity than these latter. M. Monod knows that English scientific men do not approve of the protective measures adopted by these colonies, but he thought they would be in a better position to convince foreign countries if they had succeeded in convincing their own countrymen. In answer to this point, I ventured to mention that during the great cholera epidemic of 1885, when I was at Gibraltar, the authorities explained to me that they did not approve of the quarantine measures, which they nevertheless very rigorously enforced. But in times of peace Gibraltar is nothing more than a coaling station and a barren rock. For their meat and vegetables the inhabitants are entirely dependent on their trade with the Spanish continent and with the Moors of Tangiers. Their communications with these people would have been cut off, nor would ships have been able to call for coal, if they had not strictly enforced quarantine regulations. What was done at Gibraltar was done in deference to the pressure brought to bear by other nations. M. Monod's case was stronger when he rejoined that the delegates from Canada and Australia to the London International Congress of Hygiene had spoken energetically in favour of quarantine. Yet, with all this, M. Monod is not himself in favour of quarantine. He only insists that England should not talk too loudly on the subject, for England very carefully put her own house in order before she proclaimed the principle of the abolition of quarantine; and even now, in England, measures are taken that do not fall far short of what is understood by the word quarantine. Thus in June, 1889, the *Neva*, of the Royal Mail Company, arrived at Southampton with yellow fever on board. This ship was kept in quarantine for ten days.

To bring the conversation to a practical issue I inquired what it was the French desired. M. Monod replied

Digitized by Google

that ships coming from India should be stopped on entering the Suez Canal, and that all personal linen should be disinfected by steam under pressure, as was done so rapidly and successfully on the Spanish frontier during the cholera epidemic of 1890. This need not occasion a delay of more than about five hours, and even this delay might be avoided if the ship carried a disinfecting oven, or if it could be proved that all the clothing had been disinfected in India before the passengers came on board. Should there be a case of cholera on board, then M. Monod thought the entire ship ought to be disinfected, the patients isolated, and the passengers and crew detained for five days after the last case, this being generally considered the period of incubation for cholera.

M. Monod based his demand for measures of this description on the insalubrious condition of our Indian colonies, and forthwith proceeded to quote his authorities. Dr. Simpson, medical officer of health of Calcutta, in his Report on Sanitary Measures in India in 1889-90, p. 122, says: "The decline in fever mortality is not so marked as to justify much congratulation on the improvement of public health." On page 123, Dr. Simpson says: "Each year's delay in carrying out the construction of broad streets brings with it greater difficulties and expenses; the crowding together of houses is becoming greater, the open spaces are being more encroached upon, the breathing space is gradually contracting, and the localities are progressively attaining a more unhealthy state." According to Mr. Ollivant, Municipal Commissioner of Bombay: "The most graphic description of the foul state of some districts will not give as good an idea of the truth as a quarter of an hour's visit;" and the Deputy Sanitary Commissioner of Madras, describing the town of Tirupati, says: "There are no public latrines. Portions of backyards are set apart for private resort, holes being left in the walls so that pigs may enter and clean up. People defecate anywhere, and the whole town is pervaded with the odour of pig's dung and human excreta.' In spite, however, of the want of sanitation there has been, it is said, a reduction in the death-rate of India; but M. Monod pointed out that the English themselves did not attach much faith to these figures. Sir B. Simpson, Sanitary Commissioner of the Indian Government, states that the death registration is so imperfectly conducted that it is impossible to say whether better health or more careless recording is the cause of the apparent reduction. In any case, there seems to have been no reduction in the mortality from cholera. These are the figures: In 1878 there were 318,223 deaths from cholera; in 1879, 269,336; in 1880, 118,856; in 1881, 161,712; in 1882, 350,971; in 1883, 248,860; in 1884, 287,600; in 1885, 385,928; in 1886, 208,371; in 1887, 488,788; in 1888, 270,408. M. Monod referred also to Dr. Pringle's speech at the London Congress of Hygiene, when he declared that 95 per cent. of the population of India lived in villages where their water-supply was contaminated. He alluded to the descriptions made by Mr. Ollivant of Bombay, by Dr. Holbein Herdley, and Mr. Baldwin Latham, who declared that the statistics of Calcutta and Bombay proved that the fearful mortality was due, not to the effects of the Indian climate, but to the total absence of sanitary measures. M. Monod then displayed some graphic charts, which showed that while from 1878 to 1888 the general mortality had decreased in England from 217 to 177 per 10,000 inhabitants, the mortality from cholera in India was, on the contrary, increasing. Yet English sanitarians recognise that cholera is a preventable disease. Even in India this has been proved over and over again. At the International Conference held in Rome in 1885 it was understood that the Indian Government would adopt and enforce special sanitary measures to check the development of cholera in India. At the London International Congress of Hygiene, held in 1891, Dr. Brouardel challenged the English representatives to show what had been done in India in conformity with the resolutions voted at Rome in 1885. M. Monod now maintains that if any serious sanitary progress had been made, the prevalence of cholera in India would have decreased.

Pending, therefore, more energetic action in India, M. Monod maintains it is necessary to take precautions against ships coming from India. He recognises that the Native Passenger Ships Act of 1887 constitutes an important step in the right direction. To have rendered obligatory the presence of a surgeon on board a ship carrying 100 pilgrims is an excellent measure; but why should the examination of passengers before they come on board be only facultative? Perhaps such examination will only be practised when a violent epidemic is prevailing. M. Monod insists that, in any case, pilgrims before they are allowed to embark should obtain a clean bill of health or sanitary passport. But not only should their persons be healthy, their clothes should be clean. These clothes can rapidly and without damage be sterilised by exposing them to superheated steam under pressure. This was very conclusively demonstrated by the scientific experiments of the Jury at the Universal Exposition of 1889. Thirty-four English ocean steamers have on board apparatus for this purpose. Such slight expense can render great service. If every pilgrim was examined medically and his clothes disinfected before he left India, the chances of importing cholera into the Red Sea would be very materially reduced.

Reverting to the question of quarantine, M. Monod thought that the English unwisely exaggerated when they made the sweeping assertion that quarantine could be of no service. M. Monod believed that there was something better to be done than the imposition of quarantine. In his opinion, medical inspection and disinfection offered a much more effective guarantee than the ancient system of quarantine, but to say that quarantine had never rendered any service was to fall into the other extreme. In 1891 an English ship, the *Dekkan*, arrived at Camaran with 1200 pilgrims on board. There had been cases of cholera among these pilgrims. The pilgrims went to Jeddah, and then to Mecca, and cholera followed in their wake; a severe epidemic ensued. On the other hand, the ship *Adana* left the port of Jeddah and went to Tor with 971 pilgrims on board. Eighteen deaths from cholera occurred during the journey, and six more while the passengers were landing. But at this port quarantine was imposed. Altogether more than 10,600 pilgrims were kept rigorously in quarantine, and the cholera did not travel any further. Egypt and Europe were saved. It would be difficult not to conclude that in this case quarantine was successful; therefore it is not always useless.

All these views of the questions at issue had not been sufficiently expounded in England; at least, M. Monod was tempted to believe that this was the case, because what was said by the French speakers at the London International Congress of Hygiene seemed to surprise the English members present. It was very regrettable that the question was not more fully discussed at that Congress. However, M. Monod hoped that a cordial agreement would ultimately be established between all the nations concerned, and certainly cholera would never be stamped out without the active assistance of England. Such were the main points of my lengthy conversation with M. Monod, and I was well pleased to have an opportunity of gathering from so competent an authority what were the views entertained in French Governmental circles.

Paris, Dec., 1891.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Victoria and the Albert Universities.

A MOVEMENT has lately been set on foot for the Victoria University to oppose the grant of a Charter to the proposed new Albert University for London. Sir George Young has sent a strongly worded letter to several of the leading newspapers in this district against such movement, especially as the opposition comes entirely from the medical element. He asserts that the fears expressed as to the lowering of the standard of the entrance and scientific examinations is mere surmise, and asks, "Why should two groups of educational institutions, hitherto friendly, each with ample work to do, and fair, though not superabundant, resources for doing it, be brought into violent antagonism on such insufficient grounds?" He asserts that in matters medical the Victoria University has an enormous advantage over the proposed new one, and advises the agitators "to let well alone."

The Proposed Infirmary Extension.

It was noted in these columns some time ago that a memorial had been circulated, supported by a very influential section of the subscribers to the Infirmary, asking the Board to stay their hand with regard to the proposed extension. It is expected that very shortly plans will be ready showing how the extension is to be carried out. But

Digitized by Google

the opponents thereto contend that the preparation of plans is altogether premature, the principle of extension upon the present site being the first thing to consider. The opposition to any further extension on the present site is apparently gaining strength, and with the medical staff by no means unanimous, the governing Board also divided in opinion, and a hostile feeling in the city Council as guardians of the open spaces in the city, the scheme so far does not appear very likely to be carried. A series of suggestions from the opposing memorialists for providing a new hospital as a branch of the Infirmary appears to have met with little favour by the governing body.

Salford Royal Hospital.

The financial condition of this charity has for some time caused its treasurer and managing committee some anxiety. At the present time there is a deficit of nearly £5000, and a public meeting was recently called by the Mayor of Salford to consider what means should be taken to place them in a more satisfactory position. The meeting, taken altogether, was not a marked success—the attendance was small, and the mayor, in his speech, made some remarks which did not meet with general approval. He stated, what is no doubt true, that many wealthy men in Salford contributed little or nothing to the hospital's support, and he also charged the working-classes with giving much less than might be expected from them. Mr. Mather, M.P., in the course of his speech, referred, as did influential speakers at the recent public meeting of the Hospital Sunday Committee, to the possible application in the future of public moneys from the rates for the support of hospital charities. At the close of the meeting £805 was subscribed and a general appeal made to the inhabitants of the borough for funds. The senior surgeon to this hospital, Mr. Stocks, has just resigned his post after a service of thirty-five years. When he first joined the staff in 1847 there were but ten beds, to-day there are 125; but unless more money be soon forthcoming, many of these must remain empty.

Manchester Guardians.

The Bishop of Manchester and Mrs. Moorhouse recently paid a visit to the workhouse and hospital belonging to the guardians at Crumpsall. They were not content merely with looking, but gauged the quality of the food &c. by tasting. The dinner on the day of the visit chanced to be pea soup, which his lordship pronounced to be excellent. The guardians have for some time past endeavoured to assist the sanitary authorities in their efforts to deal with dirty and insanitary districts. Two of their medical officers have written letters to the guardians, pointing out that in a large number of cases the dirty and careless habits of the people themselves are more to blame than the actual condition of the houses and properties, a conclusion which our late medical officer of health, Mr. Leigh, often arrived at.

Lead Poisoning.

At a large dye works two cases of lead poisoning have occurred, both proving fatal. The victims were young girls, and from the evidence given before the coroner it would seem that the utmost carelessness is shown by the employées, who will not avail themselves of the means provided by the firm to minimise the risk of their work, sitting down to their meals with unwashed hands, often covered with the dangerous lead pigments. It is to be hoped that these two fatalities will serve as a warning, and that more stringent rules will be enforced against those who will not protect themselves.

Removal from the Register.

The removal of Mr. Gunn's name from the Register by the Medical Council has been duly reported in your columns. A petition is being got up and largely signed for presentation to the Medical Council, asking that he may be reinstated, as it is thought that, wrong as his conduct was, many other worse offenders than he, in the matter of covering unqualified practice, go scot free.

Rabies in Lancashire.

Notwithstanding that the muzzling order is supposed to be in force in several parts of the county, more cases of rabies were reported last year than in the previous one, and the Board of Agriculture have addressed a communication to the local authorities of the districts chiefly concerned, suggesting that the regulations should be more stringently and efficiently carried out.

Cremation.

A report referring to the progress of the erection of the crematorium has been issued. It is hoped that in about three months it will be ready for use, and that Sir H. Thompson or the Duke of Westminster will be present at its completion. It is confidently stated that, taken as a whole, it will be one of the most perfect yet constructed, and that when completed the buildings will be of an ornamental character from an architectural standpoint. The cost has exceeded the first estimate, and it will require £7500 to complete the whole scheme, of which £3000 still remains to be raised. Our neighbours at Liverpool, not to be outdone by Manchester, are taking steps to provide themselves with a crematorium, so that we shall not be able to look to that city for any support, as was at first anticipated.

Manchester, Jan. 5th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The High Death-rate in Newcastle.

WITH regard to the recent high death-rate in Newcastle—viz., for the week ending the 26th ult., 44·6 per 1000,—Dr. Armstrong, our city medical officer of health, has presented a lucid report to the sanitary committee of the corporation. He shows that the deaths for the week were 161, against 82 in the corresponding week of last year, or an increase of 79. The principal factors in producing these high figures, Dr. Armstrong shows, are diseases of the respiratory organs 53, whooping-cough 10, while influenza has caused 11 deaths; phthisis has also caused 10 deaths, and measles 9 deaths. Although 51 cases of infectious diseases have been notified by practitioners during the last fortnight, they are not responsible for the high mortality, as the death-rate from scarlet fever and diphtheria has been low. It would appear, then, that our high mortality is to be attributed to the season, its changeable nature and at times low temperature acting with deadly effect on weak and aged persons.

Death from Lead Poisoning in Newcastle.

Another of these very frequent cases of fatal lead poisoning took place in Newcastle last week. It was shown at the inquest that a young married woman had worked at the white lead works for fifty-three days when she was found by the surgeon to the works to be under the influence of lead. On the Sunday before Christmas Day she was seized with convulsions and vomiting, and died on the 31st ult. It was also shown that some of the women at the works neglected to avail themselves of the precautionary measures placed at their disposal at the factory. The jury found that the deceased died from lead poisoning.

Sunderland: Contagious Diseases.

At a late inquest at Monkwearmouth the coroner for the district made some very strong remarks on the prevalence of congenital syphilis in the seaports of Sunderland and Shields. He said if the people who were agitating for the repeal of the Contagious Diseases Act could go round his district with him and see the fearful ravages which these diseases caused, and the hundreds of children born to die in these boroughs from loathsome affections before they had completed a single year of their existence, they would change their minds and hesitate to talk about a subject of which they know nothing.

Influenza.

Influenza is still very prevalent in Newcastle and Gateshead, and in most of the Tyneside and surrounding villages; it is also reported as very prevalent in Richmond, Yorkshire. The death of a very old surgeon, Mr. Richard Bowes, aged eighty-two, is announced as having occurred at the latter place. Mr. Bowes was an M.R.C.S. and L.S.A., 1831, F.R.C.S, 1871.

Sad Accident to a Durham Surgeon.

It is reported that, about nine o'clock on Monday morning last, a serious accident befel Mr. Dunlop, surgeon, of Leamside, near Durham, who by some means got in the way, near Rainton, of a train proceeding from Newcastle to the south, the engine of which struck Mr. Dunlop on the left side and knocked him on the metals, the whole of the train passing over his left leg. He was promptly removed

Digitized by Google

to the Durham County Hospital, where (in addition to the terrible injury to the leg, which it was found necessary to amputate) it was found he had received severe scalp wounds; but at the time I write he was reported as doing well.

The Gateshead Disaster.

Another death has taken place arising out of the panic at the Theatre Royal, Gateshead, in the case of a man aged twenty-six, who, in order to get out of the building, jumped from a window of the theatre, fracturing his jaw and injuring one of his legs. He was removed to the Royal Infirmary at Newcastle, where he died last night. This death makes the number of those fatally injured by the panic twelve in all—ten children and two adults.

Newcastle-on-Tyne, Jan. 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary.

THE statutory general meeting of contributors to the Royal Infirmary was held on Monday, Lord Provost Russell presiding. The annual report was submitted, from which it appears that during the year 8162 patients were admitted, while 610 remained from the previous year. Of these, there were dismissed cured 3840, relieved 2990, dismissed on other grounds 719, and died in the hospital 610. Of the total cases, 3878 were ordinary medical ones, while 4281 were surgical. The greatest number of patients in the hospital on any one date was 694, and the lowest 579. Of the total cases, 3811 were from Edinburgh, 582 from Leith, and 3766 from the country. The mortality was 5·4 per cent. after deducting the cases which died within forty-eight hours after admission, and which were due to severe injury, or were of a hopeless character when admitted. The report then discusses the finances of the institution, and regrets that the Sunday and local contributions are not increasing with the increase of population. It also expresses the hope that the country contributions may increase, and that the north of England may send them help, as several hundreds of patients come from the northern counties for advice and treatment in the infirmary. It then discusses at length the question of the proposed extension of the hospital by adding 200 beds to it. The proposals under this head are similar to those which have already appeared in the columns of Scottish correspondence, and entail an outlay of £70,000 in building &c., and an additional charge of £10,000 per annum for maintenance. The managers are willing to proceed with the extension if the contributors approve, and if the public show their sympathy with the proposal.

Health of Edinburgh.

The mortality last week was 108, and the death-rate 21 per 1000. Diseases of the chest accounted for 50 deaths, and zymotic diseases for 7. The intimations for the week comprised cases of typhoid fever 4, diphtheria 2, scarlet fever 24, and measles 12.

Jan. 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The late Mr. Wharton.

MR. WHARTON'S funeral took place on Monday morning, and was largely attended. The College of Surgeons, of which he was an ex-president, was represented by Mr. Gray Croly, President, who was attended by the mace-bearer, carrying the mace draped in black. At St. Peter's Church, where the first portion of the burial service was read, the coffin was carried from the hearse to the church by six former pupils of the deceased. Wreaths were sent by the students of the Meath Hospital, also by the lady superintendent and nursing staff, and by the inmates of the Royal Hospital for Incurables. The late Mr. Wharton was a gentleman who was greatly respected by all classes, and loved and esteemed by his late colleagues of the Meath Hospital. He held some appointments, among the rest that of medical visitor in lunacy under the Court of Chancery, which has now been conferred on Dr. J. M. Finny, President of the Royal College of Physicians.

Death from Hydrophobia.

About two months ago a boy named Beale, living in Kilkenny, was bitten by a dog, which was destroyed, and on examination was found to have been suffering from rabies. Beale and two other children bitten by the same dog were at once sent to Paris and were treated by the Pasteur me thod, and returned home about a fortnight since. On Sunday last symptoms of the dread disease appeared in the case of Beale, and he died the same evening. The other children are still quite well.

Fever in Dublin.

During the last quarter of 1891 the deaths from typhoid fever amounted to 100; from typhus fever, 4; from ill-defined fever, 2; while the mortality from scarlet fever was only 2.

Health of Ireland.

In the September quarter there were 25,834 births registered and 17,076 deaths. The birth-rate was 0·6 under the average rate for the corresponding quarter of the past ten years; and the death-rate 0·2 in excess of the average. The returns of pauperism show a decrease of 652, or 1·6 per cent., in the average number of workhouse inmates on Saturdays during the quarter, and an increase of 681 in the average number of persons on out-door relief. There were no deaths from small-pox, the mortality from measles and scarlet fever was exceptionally low, and although whooping-cough was prevalent in several districts, and enteric fever and autumnal diarrhœa caused a rather large number of deaths in Dublin and Belfast, the general mortality from these diseases was below the average for the September quarter.

New Buildings at Queen's College, Belfast.

On Jan. 4th, the erection of a new suite of buildings of great importance was commenced at Queen's College, Belfast. For many years the accommodation for students of chemistry has been quite inadequate, but this difficulty will soon cease to exist, as the Treasury have sanctioned the erection of the necessary additional buildings required, on which workmen began operations on Monday last. This new erection will form a detached block, built on a line with the north wing of the College towards the east. When completed it will contain a new lecture theatre for the chemistry class, with seats for 250 students, a large and amply fitted practical class-room, laboratories for the students, a private laboratory for the professor, a chemical museum, special rooms for water analysis, combustion, photographic chemistry, and other purposes. It is hoped a portion of the buildings will be ready for use during the next collegiate session. To the exertions of Dr. Hamilton, President of Queen's College, it is due that this grant for the erection of these buildings has been obtained.

The President of Queen's College, Galway, has retired.

Jan. 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Gratuitous Disinfection in Paris: a Description of the Modus Operandi.

A FEW years ago the Prefecture of the Seine established three disinfection depôts in this city, and regulations for their efficient working were drawn up. It may prove of interest to the readers of THE LANCET to be made acquainted with the details of these regulations, which are, I believe, strictly conformed to. In order to procure the disinfection of a fever-tainted room and its contents, the doctor or any other interested person addresses an application by telephone, telegraph, or post either directly to one of the above-mentioned establishments, or indirectly through the nearest commissary of police, who communicates at once with the officials charged with this duty, for which no fee whatever is exacted. On the receipt of the summons, a properly equipped vehicle is despatched to the address indicated. The room is first cleared of all portable objects, which are forthwith packed in stout canvas bags brought for the purpose. These packages having been deposited in the van, the room and such of its contents as are non-portable are subjected to a thorough spraying, practised with an apparatus invented by the firm of Geneste and Herscher, the liquid employed being a 1 per 1000 sublimate solution mixed with a 5 per 1000 solution of tartaric acid. The spray generated by

Digitized by Google

the apparatus is so fine that it penetrates all stuffs without deteriorating the texture. The van and its contents are then driven to the *bureau de désinfection*, into a special block of which it is admitted by a special entrance. The van is unloaded by the same employés, and the bags are carried to a room adjoining the oven-chamber. The van is then disinfected by means of the spray above mentioned. The disinfecting room is spacious, and contains ovens built into the walls, an incinerator for the destruction of useless contaminated objects, and an enormous vat for the washing of fæces or blood-stained linen before to their introduction into the ovens. This preliminary washing is done in order to prevent the stains becoming permanent. All the tainted objects—clothing, bedding, &c.—are then placed in the ovens, which are composed of vast cylinders filled with steam under a pressure of seven-tenths of an atmosphere, which brings its temperature up to 110°—115° C. or 230°—239° F. A sojourn of fifteen minutes suffices for the complete disinfection of the contents of the ovens. In order to obviate the inconveniences of the phenomenon known to physicists by the name of "calefaction," the temperature is suddenly lowered every five minutes. This manœuvre brings about the liquefaction of a certain quantity of vapour, which, moistening the objects, enables the steam to penetrate them. At the expiration of the fifteen minutes, the articles are removed from the ovens through special openings leading into a room from which all contaminated objects are rigorously excluded, and which is manned by a special *personnel*, who, having packed the purified bedding &c. in a disinfected van, convey them back to their destination. All the *employés* of the *bureau de désinfection* are dressed in canvas, and whenever the exigencies of the services render the passage of the men from the contaminated to the aseptic side of the establishment necessary, they divest themselves of their uniform and undergo a thorough washing with an antiseptic solution. A few figures will illustrate the increasing popularity of this still novel institution. At one of the *bureaux* situated in the Rue des Récollets, 274 disinfections were conducted in November as against 63 in January. During the past year the total number of disinfections for the three *bureaux* was 3414.

Cocaine as an Anæsthetic.

The frequent accidents attending the administration of chloroform render the study of the utility of cocaine employed subcutaneously as a local anæsthetic agent a matter of considerable importance. It is therefore not surprising that a discussion on its merits and demerits should crop up periodically at the meetings of such a body as the Société de Chirurgie. On the 23rd ult. the subject was again revived, and several competent authorities related their experience of this much-abused method of producing anæsthesia. M. Quénu's experience of the drug is limited to sixty operations, the strength of the solution employed being one-fiftieth, and the maximum quantity of cocaine injected in each instance being 7 centigrammes. In three subjects disquieting symptoms manifested themselves; in one (radical cure of hydrocele) these symptoms were formication of the extremities, pains, anæsthesia, and finally cerebral excitement. This surgeon now never exceeds 10 centigrammes as a dose. M. Schwartz's experience extends to 300 operations, in which the drug was employed without accident. Once, however, after the injection of a solution into the tunica vaginalis, a *commencement d'accident* occurred which was promptly obviated by the incision of the serous sac. Following Kummer (experiments on the lower animals), he ascribes great importance to the influence of Esmarch's bandage on the tolerance, in given cases, of the drug, the compression, by retarding diffusion, allowing of larger doses being exhibited. In operations on the limbs his maximum dose is 7 centigrammes; for the tunica vaginalis 10 centigrammes, and for the face and trunk 5 centigrammes. M. Regnier has witnessed two cocaine accidents (dose 1 centigramme) in his surgical practice, both patients being "cardiacs." In one, symptoms of cardiac failure (asystole) developed, and the individual died a month later. M. Moty has employed cocaine in dental practice between 5000 and 6000 times, and only on two occasions, and that quite recently has he experienced any *contretemps*. He opines that the concentration of the solution has much to do with the danger incurred. M. Reclus shares this opinion, and is persuaded that a 1 per cent. solution is strong enough for all purposes. He has utilised cocaine in over 1000 operations without encountering more than a few *alertes*. With injections of from ten to twelve centigrammes, he has frequently performed painlessly such operations as gastrotomy, castration, incision in appendicitis, &c. Care must be taken that the solution be not introduced into a bloodvessel, and the surgeon must be on his guard whenever cocaine is brought in contact with a serous surface. M. Lucas-Championnière deplores the vulgarisation of cocaine, and regards it as a much more dangerous agent than chloroform, seeing that when the latter drug is used the surgeon is present to combat untoward accidents, whereas remote consequences threatening life may follow a cocaine injection.

A New Treatment of Congenital Dislocation of the Hip-joint.

The treatment of this condition has hitherto been one of the *opprobria* of the profession. Within the last ten years, however, various operative procedures have been devised with a view of rendering locomotion more feasible; but it must be conceded that the results have been far from satisfactory. That indefatigable worker, Professor Lannelongue, has recently been led to study this disease, and on the 23rd ult. he announced to his colleagues of the Société de Chirurgie the discovery of what he considers to be a rational remedy for this malady. A dozen pathological specimens in the museum of the Hôpital Trousseau show clearly that the displacement is due to the absence or, at best, rudimentary development of a cotyloid cavity, a like absence of a capsule, and a rudimentary femoral head. By resecting the head of the femur the only result obtained is the subsequent shortening of the limb by interfering with the growth of the femur. Nor is the obvious indication to create a new acetabulum fulfilled by detaching a periostic flap. Mindful of the sclerogenic properties of zinc chloride discovered by him, M. Lannelongue has utilised his method as a means of raising a ridge of new bone round the head of the femur, and so preventing its displacement. On Nov. 17th he performed this operation on a little girl, aged three, the subject of this disease. The patient being under the influence of chloroform, and the limb being maintained in extension, twenty drops of a 10 per cent. solution of $Zn\,Cl_2$ were deposited by means of a syringe on the surface of the bone at eight different spots just above the femoral head. A week later a hard osseous ring was clearly perceptible at this situation. A fortnight after the first operation a second injection of the same solution was practised, with the effect of still further accentuating the acetabular ridge. The tiny subject of this interesting experiment was presented at the meeting. The profession will await with curiosity the ultimate result of this novel essay in the field of constructive surgery.

Death of Professor Richet.

A familiar figure has just disappeared from the surgical arena in the person of Dr. Didier Dominique Alfred Richet, honorary professor of the Faculté de Médecine, who died on the last day of the year at his château of Carqueranne, aged seventy-six. Visitors to the wards of the Hôtel-Dieu will easily recall the tall, upright form of him who was for so many years one of the leading surgical lights of this city. Although he never became really reconciled to modern antiseptic methods, he was undoubtedly a man of original ideas, and as the author of a classical work on Medico-chirurgical Anatomy, still much read by French students his name and fame will survive for many a long day. He was a member of the Institute, and an ex-president of the Académie de Médecine, which body suspended its meeting yesterday as a mark of respect to his memory. M. Richet, who was for many years Professor of Clinical Surgery at the Faculty, leaves a distinguished son, M. Charles Richet, also a professor (of physiology) at the Paris Faculty.

Paris, Jan. 6th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Rohrbeck's Disinfector.

ON the 17th ult. Count Zedlitz, Prussian Minister of Educational, Ecclesiastical, and Medical Affairs, paid a visit to the great Berlin slaughter-house to see a disinfecting apparatus invented by Dr. Hermann Rohrbeck, which has

Digitized by Google

been in use there for some time past for experiments bearing on the disinfection and utilisation, or, if necessary, destruction, of the flesh of diseased animals. His Excellency was accompanied by Koch's successor, Professor Rubner; Dr. Schönfeld, Privy Adviser on Medical Affairs; Privy Advisers Pistor and Friedheim, &c. Drs. Rohrbeck and Duncker, the latter of whom is the chemist of the Cattle and Meat Inspection Office, explained the apparatus. It differs very materially from other disinfectors, and completely solves the problem of making condemned meat fit for human food, or of converting it, if that is impossible, into manure-powder. Its peculiarity is that it prevents the access of over-heated steam to the objects to be disinfected; and, secondly, by means of a condensing apparatus drives all remnants of air out of them, thus facilitating the penetration of the steam to their inmost parts. This deep and thorough penetration is of extreme importance, for it is just in the inmost parts of pieces of meat, for instance, that it is specially difficult to raise the temperature to a height sufficient to kill bacteria or animal parasites. With Rohrbeck's apparatus this purpose is attained with comparative ease and rapidity, as is proved by pyrometers placed in the inmost parts of pieces of meat by means of larding pins, and electrically connected with bells outside of the apparatus, which they set a-ringing the moment the temperature in the interior of the meat reaches the requisite degree. Maximum thermometers inserted beside the pyrometers show the highest degree of heat attained. The Minister and the gentlemen who accompanied him followed the demonstration with keen interest, and it is probable that this admirable apparatus, which seems to be one of considerable economic as well as sanitary value, will soon be widely introduced.

Venereal Diseases in Berlin.

At a meeting of the German Society for Public Hygiene, held on Dec. 14th, Dr. A. Blaschko spoke on the diffusion of venereal diseases in Berlin, and arrived at the surprising conclusion, based on comprehensive and mostly official statistics, that since 1860—i.e., four years after the abolition of brothels—there has been a considerable and constant decrease in venereal diseases in Berlin, especially in syphilis; but that, notwithstanding this decrease, the diffusion of these diseases among the population of this city is still very extensive, 10 to 12 per cent. of the population being syphilitic. He criticised the regulations of the Sick Fund Act, and proved that they, far from producing the intended "moral" effect, only gave occasion to dangerous delay, concealment, and further dissemination of syphilis. In the further course of his speech Dr. Blaschko advocated the admission of venereal patients to all public hospitals, and declared that the inhumane treatment of such patients reminded one of mediæval prejudices. It was high time, he said, that these patients should be treated, not as sinners, but as patients.

Salophen.

At a recent meeting of the Berlin Medical Society Dr. Paul Guttmann of the Moabit Hospital recommended a new medicament called Salophen. It is a finely crystalline substance, easily soluble in ether and in alcohol, but not soluble in water. It consists of salicylic acid and acetyl-paramidophenol in almost equal parts. Six to eight grammes can be given daily without injury to the patient. In acute articular rheumatism it soon removes the pain and the swelling. Sometimes, however, it fails to produce these effects, and it does not protect against relapses. In chronic articular rheumatism also it may be tried with success. It has a slight antifebrile effect.

Death of Professor Weber of Bonn.

This eminent aural surgeon died on the 30th ult. He was the first to perform the operation of cutting the tendon of the tensor tympani muscle. This operation fell into discredit for some time, but is now performed by Kessel of Jena and Cholewa of Berlin. Another of Weber's contributions to science is his "experimental demonstration of a free communication of the endolymphatic and perilymphatic chambers of the labyrinth of the human ear with extra-labyrinthic intra-cranial cavities." A third is his treatise on the nature and curability of the most frequent form of progressive dulness of hearing. In the monthly periodical for Otiatrics (*Monatsschrift für Ohrenheilkunde*), which was founded by him in conjunction with Voltolini, Gruber, and Rüdinger in 1867, he published many of his clinical observations. He invented an ear microscope which magnifies the tympanic membrane fifteen times and enables the surgeon to see its power of vibration. He resigned his professorship at Jena in 1885 owing to delicate health, and went to live at Wiesbaden, whence he removed to Bonn.

Professor von Rothmund.

Professor Franz Christof von Rothmund, the oldest of the German surgeons, died at the end of last month, aged eighty-nine. Nussbaum was a pupil of his.

The well-known anatomist, Wilhelm Krause, has resigned his professorship at Göttingen, where he has taught for about thirty years.

Dec. 15th, 1891.

Obituary.

PROFESSOR JOHN WOOD, F.R.S., F.R.C.S. ENG.

WE announced in our last issue that this distinguished anatomist and surgeon died on the 29th ult., at his residence in Wimpole-street. For the past three years he had been obliged to give up his public and private professional engagements in consequence of a slow, but progressive, attack of paralysis agitans. He was born at Bradford, in Yorkshire, in 1825, and was the youngest son in a large family. He was educated at a private school (Mr. E. Capon's) in that town, and was then articled to a solicitor. About this time he had a severe fall and injured his hip, resulting in a permanent shortening and deformity. This accident, combined with a distaste for the law, determined him to leave the legal and to study for the medical profession. He was consequently apprenticed to the senior surgeon of the Bradford Infirmary, and studied there, until in October, 1846, at the age of twenty-one, he entered the medical department of King's College. His studentship was marked by an extraordinary and rapid success, for he obtained the Junior, Second Year, and Senior Scholarships in successive years, in addition to the Warneford prize and some class prizes and certificates of honour. In 1848 he passed the First M.B Examination at the University of London, obtaining the second place in honours in Anatomy and Physiology, and was awarded the gold medal—the scholarship being won by Dr. J. S. Bristowe; he was also placed in honours in Organic Chemistry and in Materia Medica, but he did not further pursue a University career. He became a member of the Royal College of Surgeons and a Licentiate of the Apothecaries' Society in 1849, and in 1850 was appointed house surgeon to King's College Hospital. In the following year John Wood and his friend and contemporary Hyde Salter were selected to fill the valuable posts of demonstrators of anatomy in King's College under Professor Partridge, in succession to William Brinton and Henry Lee. Salter soon gave up the teaching of anatomy, but Wood practically lived in the dissecting-room until 1870, when he followed Sir William Fergusson in the chair of surgery. It was during this period that Mr. Wood made a world-wide reputation by his dissections to elucidate the anatomy of hernia, with a view to its radical cure; by his monograph on the Pelvis, in Todd's Cyclopædia of Anatomy and Physiology, which is one of the ablest articles in that most excellent dictionary, followed by an ingeniously reasoned theory on the cause of Obliquely Ovate Pelvis, at the Pathological Society in 1856; and by his elaborate papers on Muscular Abnormalities, which he read year after year before the Royal Society from 1864 to 1868. The amount of labour involved in the preparation of these papers will be shown by a single quotation: "The total number of abnormalities in the 102 subjects is 981, of which 623 are in the 68 males and 358 in the 34 females. The number found on both sides is 623, of which 414 are in the males and 209 in the females. The number found on the right side only is 176, of which 108 are in the males and 68 in the females. The number found on the left side only is 182, of which 101 are in the males and 81 in the females, making a total of 358 one-sided specimens." In 1870 his more remarkable contribution to abnormal myology, on the "Muscles of the Neck and Shoulder," was published in the Philosophical Transactions, and the close analogy between some of these variations and the regular muscles of the lower animals was emphasised by the numerous dissections made on all kinds of vertebrates by Mr. Wood during a long series of years. He was soon after-

Digitized by Google

wards elected a Fellow of the Royal Society, and his observations were referred to by Mr. Darwin in his argument on the descent of man. His knowledge of topographical anatomy is well shown in a paper in the first number of the *Journal of Anatomy and Physiology*, in which he corrected some erroneous opinions on the position of the heart and large vessels then current in the text-books. During the earlier part of this time Mr. Wood was teaching anatomy to private pupils as well as publicly, and nobody could excel him in the steady, careful, and painstaking manner in which he discharged his duties; and in addition to this conscientiousness, every real student was struck by his brilliancy of exposition, his skill in draughtsmanship, and his knowledge of details. Mr. Wood learnt his anatomy from the subject and always taught it on the subject, and frequently—for he was a rapid as well as an able dissector—made the necessary dissections himself for his demonstrations. No one who worked in the dissecting-room of King's College under Mr. Wood could fail to be infused with some of his earnestness. This extended anatomical work mainly led to his success as a surgeon. In 1856 he was elected assistant surgeon to King's College Hospital, in 1870 he became full surgeon, and in 1889, when his health began to fail, he was appointed one of the consulting surgeons, whilst for many years past he had been a member of the committee. He never occupied the chair of anatomy in King's College, for Professor Partridge was still alive when, on the resignation of Sir Wm. Fergusson, the vacant professorship of surgery was offered to Mr. Wood in 1871. His lectures on systematic surgery were models of well-arranged detail and clear exposition, and it was a matter of much regret among his pupils that he should have preferred a joint professorship of clinical surgery with Sir Joseph Lister in 1877 to continuing the systematic teaching for which he was so specially adapted. In 1870 he was elected an honorary Fellow of King's College, and in 1889 Emeritus Professor of Clinical Surgery, after thirty-eight years of assiduous, almost daily, work and teaching at King's College and King's College Hospital. Mr. Wood's most important contribution to practical surgery was the introduction of a special method for the radical cure of hernia—inguinal, crural, and umbilical—for which he obtained the Jacksonian prize essay in 1861, and which he afterwards published in an enlarged form in 1863. This operation was entirely based on his own dissections, and no abler and more precise account of the parts concerned can be found even in our most modern anatomical works. He gained a most extensive reputation through his success in devising and performing this operation—a success so great that boys who had been refused by the naval authorities were afterwards accepted on having had this radical cure performed on them by Mr. Wood. No one can at the present day deal with the subject of hernia without having to estimate the value of Wood's operation, and the departures from it are only modifications which are the natural outcome of the antiseptic methods of treatment now in general use. In the Hunterian Lectures at the Royal College of Surgeons in 1885 Professor Wood referred to the great success which attended the operation, not only in his own practice, but in that of many of his pupils. Professor Wood also devised and performed a new operation for relieving extroversion of the bladder with epispadias, and it was in such cases as these that his ingenuity in planning, his precision in making the incisions, and his skill in dissecting the flaps were so conspicuous. In plastic surgery he was a master, but he performed the ordinary operations of every-day surgery with rare calmness and dexterity. He always described fully the steps of every operation he performed, and his terse and clear exposition, his striking diagrams, and his mastery of anatomical detail gave every visitor to the operating theatre of King's College Hospital an unusual surgical experience. He strongly urged the use of antiseptic dressings in surgery. He largely contributed to Druitt's "Surgical Vade Mecum," especially to the edition of 1878. He became a Fellow of the Royal College of Surgeons by examination in 1854, was elected a member of the Council and of the Court of Examiners in 1879, Hunterian Professor in 1884, and vice president in 1885. He filled at various times the offices of Examiner in Anatomy and afterwards in Surgery at the University of London, and in Surgery at the University of Cambridge, and the Royal Colleges of Physicians and Surgeons of England. He had been the President of the Metropolitan Counties Branch of the British Medical Association, Vice-President of the Medico-Chirurgical and Pathological Societies, and was an Hon. Fellow of the Swedish Medical Society.

He was buried at Kensal Green Cemetery on the 4th inst., Mr. Jonathan Hutchinson representing the Royal College of Surgeons, Mr. F. G. Hallett representing the Conjoint Examining Board in England. Professors Christopher Heath, Henry Smith, Bentley, and many of his former colleagues and pupils were present.

WM. BARR BROWN, M.R.C.S., L.S.A.

THE death on Christmas Day of Mr. Barr Brown at the age of eighty-five removes from among us one of the finest examples of a class of practitioner now fast dying out. To those of his friends who have been in touch with his sufferings of the last two years his death will be more a relief than a surprise. His father was a gentleman farmer in Lincolnshire, and he himself was educated at St. Bartholomew's Hospital. In 1832 he went to Ascot, where for nearly sixty years he was actively engaged in practice. Originally a Court suburb to Windsor, it has since grown into a large residential neighbourhood. So complete was his hold on this important and extensive district that to the time he relinquished practice no one ever attempted to dispute his supremacy. It would be difficult to find a man who, over so great a space of time, obtained and retained such complete confidence, respect, and affection amongst all classes as he did alike in his home, among his patients, neighbours, or brother medical men. Though by nature and education of simple tastes and of rare singleness of mind, the great confidence extended to him by a large *clientèle*, mostly of the upper ranks in society, gave him a very extended knowledge of human nature. This, coupled with an intelligence of no mean order and an honest endeavour to be in touch with all that was practical and sound in his profession, made him prominent as a skilful practitioner, and his independence of thought and action, tempered by his kindliness of disposition and devotion to duty towards both rich and poor alike, will ever mark him as a Christian gentleman. In his earlier days he was a keen sportsman and lover of Nature, and few men fitted a horse better across country, whether riding to hounds or as a short cut to his patient's bedside. As evidence of the appreciation of his qualities and character, when about twelve years ago a desire was evinced on the part of his friends and patients to offer some expression of their sympathy and regard at a time of sore domestic bereavement, it was accompanied by a purse of nearly £1500, and this within a fortnight of the suggestion being made. It is doubtful if ever a more substantial testimonial was received by a general practitioner. Those who have had the privilege of being associated with him in his practice, and the advantage of his example as a guide, will ever hold his name in affectionate remembrance.

JAMES H. WHARTON, M.B. T.C.D., F.R.C.S.I.,

OF DUBLIN.

WE record with regret the death of an eminent Dublin practitioner, which occurred last week at his residence, 28, Upper Merrion-street, at the age of seventy-six. Mr. Wharton had been in failing health for many months past, and had resigned some appointments, but the immediate cause of his death was bronchitis. He graduated in arts in Dublin University in 1837, and in 1868 obtained the degrees of Master of Arts and Bachelor of Medicine, while in 1845 he obtained the Fellowship of the Royal College of Surgeons in Ireland. He acted for many years as a member of council of the College of Surgeons, and was elected president for the year 1871-2. For many years he was associated with the Ledwich School of Medicine, and in 1846 was elected lecturer on materia medica, and in 1858 lecturer on surgery, which post he held until 1880, when he retired. In 1858 he succeeded the late Mr. Thomas Ledwich as surgeon to the Meath Hospital, which appointment he resigned a couple of years since. Mr. Wharton was surgeon to the Royal Hospital for Incurables, to Bloomfield Retreat, Pleasants' Asylum, and a visitor in Lunacy under the Court of Chancery. He was also surgeon to the Cork-street Fever Hospital, and for some time an examiner in surgery in the University of Dublin and the Queen's University in Ireland. Mr. Wharton married a daughter of the late Sir William Brady.

Medical News.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—Dr. J. H. Skeen, Assistant Medical Officer, Stirling District Asylum, passed the examination on Psychological Medicine held in Aberdeen in December.

LIFE ASSURANCE MEDICAL APPOINTMENTS.—Dr. Arthur T. Davies and Dr. Francis G. Penrose have been appointed medical officers of the Westminster and General Life Assurance Association.

TYPHOID FEVER IN ATHENS.—A serious epidemic of typhoid fever has broken out in Athens, traceable, it is said, to the stoppage of drains, consequent on the construction of the railway tunnel now being run under the lower part of the city.

PRESENTATION TO THE LORD MAYOR.—On the 1st instant the Master (Dr. W. Sedgwick Saunders), the Wardens, and the Court of the Borderers' Livery Company, waited upon the Lord Mayor at the Mansion House, and presented him, as a member of their body, with an address of congratulation on his attaining the dignity of chief magistrate of the city of London. The address, illuminated, was deposited in an oblong silver casket, of the Queen Anne period, bearing a suitable inscription. His Lordship acknowledged the presentation in a few appropriate remarks.

SANITARY INSPECTORS' ASSOCIATION.—The New Year's address to the members of this body was given by Dr. B. W. Richardson, who congratulated them on the position they had attained in the estimation of the public, and on the fact that the Board of Trade had permitted the society to be enrolled as one limited by guarantee, which was equivalent to incorporation. He advised the formation of a school in connexion with the society, in which physiology, natural history, the principles of hygiene &c., might be taught, and concluded by referring to the present improved condition of the public health in the aggregate as compared with that of former generations.

GLOUCESTER INFIRMARY.—At the quarterly meeting of the governors, held on the 31st ult., Mr. A. M. Sydney-Turner resigned his position on the medical staff owing to ill-health. His resignation was accepted, and his valuable services to the institution for thirteen years appreciatingly recognised. Mr. J. D. Birchall passed a high encomium on the chairman of the governors, Dr. Ancrum, stating that he had had Dr. Ancrum's portrait painted by the Hon. J. Collier for presentation to the infirmary. The portrait, a half length one, and an admirable likeness, was then unveiled. On behalf of the institution the portrait was accepted by the officials connected with the infirmary, and by the mayor of the city for the citizens.

THE YELLOW FEVER IN BRAZIL.—The *La Plata*, which arrived at Southampton on the 3rd inst., reports that the yellow fever attacked the chief steward, and also one of the firemen. Both had been buried at sea. Four other members of the crew were sufferers and one passenger, but they were put ashore, and were being treated in hospital. The *La Plata* also brought home a number of English sailors who had been left behind by their vessels through attacks of the fever, and who had been sent home by the English Consul. Reports from Santos give serious accounts of the ravages made by the fever, and the situation is becoming all the more acute because of the crowds of destitute emigrants who are flocking into the port, begging to be sent home.

PRESENTATIONS.—Mr. Richards, on recently resigning his appointment of medical superintendent of the female department of the Hanwell Asylum, after twenty-three years' service, was presented by the nurses with a valuable dressing-bag as a token of the esteem in which he was held by the donors. He was also the recipient of tangible proofs of regard from his brother officers.—Dr. Edward Bland of Sandiacre, Derby, has been presented by the inhabitants of the town and district, in testimony of their high esteem and respect, after practising there for the past forty years, with a handsome brougham, a set of silver-mounted harness, a coachman's livery, a portrait of himself, painted by Mr. Warsop of Nottingham, and a beautifully illuminated address

WELLINGTON COLLEGE.—In connexion with the question of the sanitary condition of this College a meeting of parents and guardians is announced to be held at noon to-day (Friday) in the theatre of the Royal United Service Institution, Whitehall-yard, S.W.

FOOTBALL CASUALTIES.—On Saturday, at Leicester, whilst playing in a match between the London-road Mission and St. John's (Leicester) Club, a youth fractured his leg below the knee and was taken to the Infirmary.—In a Newton Heath and Canadians match a player fractured his leg and was removed to the Royal Infirmary.

DR. E. BOTTINI, whose elevation to the Italian Senate we lately announced, and whose paper on "The Surgical Cure of Cavernous Angioma of the Cheek" (THE LANCET, Sept. 20th, 1890), must be fresh in the remembrance of our readers, lies dangerously ill of influenza at Milan. Drs. Rozzonico, Ferrara, Simonetta, and Gatti have met in frequent consultation, and their latest bulletin was such as to cause the gravest anxiety.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.—The medical statistics of the 2351 in-patients for the year 1891 are as follows: Diseases of the locomotory system, 1936; morbus coxæ, 4; diseases of the nervous system, 306; diseases of the hæmopoietic system, 40; diseases of the circulatory system, 1; diseases of the respiratory system, 31; diseases of the alimentary system, 10; diseases of the urinary system, 5; diseases of the integumentary system, 18.

THE LATE MR. CONWAY, TIPPERARY.—Mr. Daniel Conway, L.S., L.M. Dub., medical officer of the Tipperary Dispensary, died of pneumonia on the 25th ult., contracted in discharge of his medical duties. On the previous Sunday he visited a patient at Solohedby, where it is believed he contracted the disease. On the following Tuesday night he left his sick bed to attend the same patient, and on Wednesday doctors were called in to attend him, but their efforts were unavailing, and he died early on Christmas Day. He was slightly over twenty-eight years of age.

ROYAL HANTS INFIRMARY.—A specially convened meeting of the governors was held on the 23rd ult., the object being to rescind Rule 58, which had lately been agreed to, the effect of which was, that the five members who had attended the fewest number of meetings of the Committee of Management shall retire annually, and not be eligible for re-election for one year. Some demur had been expressed to this alteration, and the Committee of Management now brought forward an amended proposal, that the five senior members shall retire annually, but shall be eligible for re-election. Considerable discussion ensued, and the committee's recommendation was adopted, adding a rider that the five retiring members should be put up *seriatim* to the vote of the governors instead of *en bloc*, which was formerly the case.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BISDÉE, A. J., M.R.C.S., has been appointed Medical Officer for the Sixth Sanitary District of the Ware Union.

BOOTH, FRED., M.B., C.M. Aberd., has been reappointed Medical Officer of Health for St. Anne's-on-the-Sea.

BRADEN, J. H., M.R.C.S., has been reappointed Medical Officer of Health for the Borough of Lewis.

BREMNER, JAS., M.B., C.M. Aberd., has been appointed a District Medical Officer of the Strand Union.

BROGDEN, J. E., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the Castell Caerdydd Lodge of the Manchester Unity of Oddfellows.

BROWN, F. L. H., M.B., C.M. Edin., has been appointed Medical Officer for the No. 1 Sanitary District of the Coventry Union.

BUTTERFIELD, HARRIS, M.R.C.S., has been appointed Medical Officer of Health for the Cranbrook Union.

CLARKSON, H. G. H., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Southern Sanitary District of the Pateley-bridge Union.

EVANS, R. W., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health for the Borough of Wrexham.

FELCE, STAMFORD G., B.A., M.B., B.C. Cantab., has been appointed Assistant Medical Superintendent to the St. Saviour's Union Infirmary, East Dulwich, vice T. Fisher, M.D.

GIBBONS, H., M.B., C.M. Aberd., has been appointed Medical Officer of Health to the Desborough Local Board.

Digitized by Google

GREEN, C. D., M.D. Lond., L.R.C.P., M.R.C.S., D.P.H., has been reappointed Medical Officer of Health to the Edmonton Local Board.

HARRISON, JOHN, L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Braintree Sanitary District of the Braintree Union.

HENRY, JOHN P., M.D., B.Ch. Dub., L. & M.R.C.P. Irel., has been appointed Medical Officer to the Blackheath-hill and Cold Bath Districts of the Miller Hospital and Royal Kent Dispensary.

JONES, FELIX F., M.R.C.S., has been reappointed Medical Officer of Health for the Llanfyllin Rural Sanitary District.

JOYNES, F. J., M.R.C.S., has been reappointed Medical Officer of Health for the Dursley Rural Sanitary District.

KIRTON, C. STANLEY, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer and Vaccination Officer for Leigh, Essex.

LAWRENCE, ALFRED, M.R.C.S., L.R.C.P., L.M., has been appointed Surgeon to the Fever Hospital, East London, Cape of Good Hope.

NAYLOR, W. R., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Middleham Sanitary District of the Leyburn Union.

POLSON, WM., M.B., C.M. Edin., has been appointed Medical Officer for the Felton Sanitary District of the Alnwick Union.

RIDDALL, J., L.F.P.S. Glasg., has been appointed Medical Officer of Health for the Ayr Burgh, vice Dobbie, deceased.

RIDLEY, WALTER, M.B., M.S. Durh., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Hospital for Sick Children, Newcastle-on-Tyne.

RODERICK, SYDNEY JAS., M.B., C.M. Edin., has been appointed Medical Officer of Health for Llanelly.

ROWELL, GEORGE, F.R.C.S., has been appointed Assistant Anæsthetist to the Dental Hospital of London.

SMITH, HENRY, M.B., B.S. Durh., has been reappointed Medical Officer of Health for the Brandon and Byshottles Urban Sanitary Districts.

SOMERVILLE, J. W., M.B., C.M. Edin., has been appointed Medical Officer of Health for Galashiels.

STEPHEN, J. S., M.B., C.M. Edin., has been appointed Medical Officer for the Morland Sanitary District of the West Ward Union.

STONHAM, H. A., M.R.C.S., L.R.C.P., has been appointed Resident Obstetric Assistant Physician to the Westminster Hospital.

SWIFT, T. C., M.R.C.S., has been appointed Medical Officer to the Foundling Hospital, vice H. W. Statham, resigned.

TABOIS, FRED. W., L.D.S. Eng., has been appointed Dental House Surgeon to Guy's Hospital.

TURNER, J. A., M.B., C.M. Edin., D.P.H. Camb., has been reappointed Medical Officer of Health for Melton Mowbray.

VIDLER, A. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of the Workhouse and No. 1 Sanitary District of the Rye Union.

WARD, J. A., M.R.C.S., has been appointed Assistant Medical Officer to the Infirmary of the Parish of St. Luke, Chelsea, vice Lift, resigned.

WILLIAMS, E., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health for the Mold Rural and Urban Sanitary Districts of the Holywell Union.

WRIGHT, J. H., M.B., C.M. Edin., has been appointed Medical Officer of Health for the Borough of Kelso.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

ANCOATS HOSPITAL, Manchester.—Resident House Surgeon. Salary £50, with board and washing.

BOURNEMOUTH FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Assistant Medical Officer. Commencing salary £100. (Apply to Mr, Honerseil, 50, Old Christchurch-road, Bournemouth.)

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, London, S.W.—Clinical Assistantship.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Resident Medical Officer. Salary £100 per annum, with board &c. (Apply to the Secretary, at the Office, 24, Finsbury-circus, E.C.)

DENTAL HOSPITAL OF LONDON.—MEDICAL SCHOOL.—Medical Tutor. Salary £40 per year.

FOLKESTONE FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Medical Practitioner. Salary £200 per annum, with an additional fee for midwifery cases. (Apply to the Secretary, 47, St. Michael's-street, Folkestone.)

GENERAL INFIRMARY, Northampton.—House Surgeon. Salary £125 per annum, with furnished apartments, board, attendance, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon for one year. Salary £50 per annum, with board and residence in the Hospital.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—House Surgeon.

METROPOLITAN ASYLUMS BOARD.—Second Assistant Medical Officer to the Leavesden Asylum for Imbeciles, near Watford, Herts. Salary £120 per annum, rising £10 annually to £150, with board, furnished apartments, and washing. (Apply to the Clerk, Offices, Norfolk House, Norfolk-street, Strand, W.C.)

MIDDLESEX HOSPITAL, W.—Medical Registrar.

QUEEN'S COLLEGE, Belfast.—Lecturer on Pathology.

ROYAL SOUTH HANTS INFIRMARY, Southampton.—Assistant House Surgeon. Board and rooms provided.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon for six months. Board, lodging, and washing provided.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—Assistant House Surgeon. Board, residence, and washing provided.

ST. GEORGE'S HOSPITAL, W.—Lecturer on Aural Surgery.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea, S.W.—House Surgeon to the In-patients. Honorarium £50 per annum, and board and lodging in the hospital provided.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea, S.W.—House-Physician to the In-patients. Honorarium £50 per annum, with board and lodging in the hospital.

Births, Marriages, and Deaths.

BIRTHS.

BATTISCOMBE.—On Dec. 25th, at Sandlings, St. Mary Cray, Kent, the wife of C. G. Battiscombe, M.B., C.M., of a daughter.

CLARKE.—On Jan. 3rd, at Estcourt-road, Fulham, the wife of William F. Clarke, M.D., B.S. Lond., of a daughter.

KIDD.—On Jan. 1st, at Merrion-square, Dublin, the wife of George H. Kidd, M.D., President of the Royal Academy of Medicine in Ireland, of a daughter.

PESKETT.—On Dec. 31st, at Oakover, Burnham, Somerset, the wife of A. W. Chalmers Peskett, M.A., M.B., B.C. Cantab., of a daughter.

RABAGLIATI.—On Jan. 1st, at Walmer-villas, Bradford, the wife of Andrea Rabagliati, M.D., of a son.

ROWLEY.—On Nov. 26th, 1891, at Te-Awamutu, Auckland, New Zealand, the wife of Charles Rowley, M.R.C.S. Eng., of a son.

SEQUEIRA.—On Jan. 4th, at Arlington-villas, Fairlop-road, Leytonstone, the wife of G. W. Sequeira, M.R.C.S., L.S.A., of a daughter.

MARRIAGES.

DAKIN—LEWIS.—On Jan. 2nd, at St. Cuthbert's, South Kensington, William Radford Dakin, M.D., of Welbeck-street, W., son of the late John Dakin, of Congleton, Cheshire, to Sylvia Concanen, elder daughter of Francis Theodore Lewis, Nevern-square, S.W.

EARLE—ISAACS.—On Nov. 18th, at St. Alban's Church, Santa Cruz Mts., Jamaica, Edward Robert Charles Earle, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., eldest son of Edward Muirhead Earle, Esq., of Jamaica, to Lydia Isabel, second daughter of Charles Earle Isaacs, Esq., of Mount Olivet, Santa Cruz Mts., Jamaica.

GRIFFITHS—WATERS.—On Dec. 31st, at Llangammarch Parish Church, by the Rev. T. Williams, uncle of the bridegroom, assisted by the Rev. W. Williams, Vicar, John Griffiths, surgeon, Oswestry, to Caroline Sarah Winston Waters, youngest daughter of the late Dr. Waters, Waverley Lodge, Jersey.

DEATHS.

ALLAN.—On Jan. 2nd, at St. Leonards-on-Sea, James Allan, F.R.C.S., Surgeon-Major (Retired) Indian Army, aged 63.

BOWES.—On Jan. 1st, at Richmond, Yorkshire, Richard Bowes, M.R.C.S., aged 82.

BRADLEY.—On Jan. 2nd, at Brunswick-place, Brighton, Charles Lawrence Bradley, F.R.C.S., F.L.S., aged 73.

CHRISTIE.—On Jan. 2nd, at Hillhead, Glasgow, James Christie, M.D., F.F.P.S. Glasg., aged 36.

COGSWELL.—On Jan. 2nd, at York-terrace, Regent's-park, Charles Cogswell, M.D., aged 78.

DICKINSON.—On Dec. 31st, at Brook House, Uffculme, Devon, William Wood Dickinson, M.R.C.S. Eng., and L.S.A. Lond., aged 52.

GREENE.—On Dec. 30th, at St. Leonard's-terrace, Chelsea, Edward Campbell Greene, B.A. Oxon., M.R.C.S., L.R.C.P.

RUDDERFORTH.—On New Year's morning, suddenly, at Lyndhurst, Hampton-hill, Dr. E. H. Rudderforth, aged 78.

PRATT.—On Jan. 2nd, at the Willows, Wolverhampton, George Arthur Pratt, M.R.C.S., L.R.C.P., aged 29.

RUSSELL.—On Jan. 1st, at Thurles, Co. Tipperary, John Russell, L.R.C.P. Irel., L.M., M.R.C.S., aged 77.

WYNTER.—On Dec. 26th, at his residence, Winslow, Bucks, John St. Thomas Wynter, M.R.C.S., aged 83.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METROPOLITAN ASYLUMS BOARD.

Return of Patients remaining in the several Fever Hospitals of the Board at Midnight on January 5th, 1892.

Medical Diary for the ensuing Week.

Monday, January 11.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-sq., W.C.).—8 P.M. Mr. Christopher Heath: Epithelioma of the Jaws. Casual Communications The President's Valedictory Address.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. T. Churton (Leeds): Remarks on a case of Cerebral Hæmorrhage, with Demonstration of Brain.—Mr. Bruce Clarke: The Radical Cure of Prostatic Obstruction by the Galvano-cautery.—Dr. Frank J. Wethered: The Diagnostic and Prognostic Value of Tubercle Bacilli in the Sputum.

Tuesday, January 12.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.

SOCIETY OF ARTS.—4.30 P.M. Mr. Ernest Satow: The Laos States of Upper Siam.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Mrs. French-Sheldon: Customs among the Natives of East Africa from Teita to Kilimegalia, with special reference to their Women and Children (illustrated by optical lantern).

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Dr. John Phillips: On Tetanus as a Complication of Ovariotomy.—Mr. Henry J. Tylden: A Critique on Recent Researches in Diabetes Mellitus, with an Original Note on the Pathology of the Pancreas.

Wednesday, January 13.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.

CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.

ST THOMAS'S HOSPITAL.—Operations, 1.30 P.M; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

SOCIETY OF ARTS.—7 P.M. Professor John M. Thomson: Three States of Matter—Solid, Liquid, and Gaseous. (Juvenile Lecture.)

HUNTERIAN SOCIETY.—8.30 P.M. Dr. Patrick Manson: On a Method of Operating in Abscess of the Liver.—Mr. F. R. Humphreys: On a case of severe Renal Hæmorrhage after Parturition, with Phlegmasia Dolens later on.

Thursday, January 14.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Annual Meeting.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. Louis Jones: Electricity as an Aid to Medical and Surgical Diagnosis and Treatment.

Friday, January 15.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, January 16.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department 9.15 A.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

FEES UNDER THE NOTIFICATION ACT.

C. W. J.—Our correspondent is entitled to, and can compel payment of, notification fees in *all cases* of the diseases specified under the Act—namely, small-pox, cholera, diphtheria, membranous croup, erysipelas, the disease known as scarlatina or scarlet fever, and the fevers known by any of the following names: typhus, typhoid, enteric, relapsing, continued, or puerperal fever. Of course we infer that the Act has been adopted by the particular district. The poverty or wealth of the patients has nothing to do with the liability of the authority The notification is in the *public* interest, and the public must pay.

Dr. J. Herbert Stowers.—We quite agree with our correspondent that the method of distributing such cards is wrong and to be deprecated, and that it has an undesirable tendency to divert assistance from more desirable institutions. No doubt at the proper time the Hospital Sunday and Saturday Funds will take due note of it.

Dr. Bronner (Bradford).—The paper will appear in an early number.

THE CLIMATE OF JAVA.

To the Editors of THE LANCET.

SIRS,—In the current number of THE LANCET "Viator" asks for information concerning the climate of Java, and asks whether a stay of a few weeks would be injurious to health. From my experience of Java I should say that a visit of such short duration could not possibly injure anyone. The climate is delightful in many respects, and fairly even all the year round as regards the heat. Like most Eastern countries, it has its hill-station, which is fortunately quite close to Batavia, a few hours' run only, where there is a very comfortable hotel. Batavia is a lovely eastern city, rich in tropical foliage, as is the entire island. Samarang and Surrabaya are lovely places, luxuriant in tropical foliage and palms, but very malarious from their low-lying situations. The visitor is all right in Batavia at the Hôtel de Nederlands, where I stayed; and if it is too hot, he may run up the hill—a kind of Javanese Simla. I have travelled all through the East (India, &c.) and Far East (China, Japan, &c.), but saw nothing so beautiful in the way of true tropical scenery as is found in the Malacca Straits and Java—the home of the mangostan, the fruit of all fruits, not obtainable anywhere else, either by natural growth or importation.

I am, Sirs, yours truly,

Albion-road, N.W., Jan. 2nd, 1892. W. SHEPPERSON, F.R.G.S.

SIR W. J. MOORE'S PAPER ON "FAMINE AND DISEASE."

To the Editors of THE LANCET.

SIRS,—I shall be obliged if you will kindly allow me to correct a mistake which occurs in the report of my paper on "Famine and Disease" (THE LANCET, Jan. 2nd). Your report reads as follows:—"From the principality of Malwa alone [which should have been *Marwar*] it is estimated that one million of people emigrated, taking with them one and a half million of cattle. The anti-opiumists had said that the extending cultivation of opium in Malwa had caused the famine in the neighbouring province of Rajpootana; but the fact was that tens of thousands of human beings, and more cattle, found food in the opium-growing state of Malwa." Marwar is the largest and most westerly State of Rajpootana. Then towards the east are the Aravelli range of mountains, separating Marwar from Meywar. Still more easterly is Malwa. The similarity of these names often causes printers' errors; and the substitution of Malwa for Marwar in your report alters what I wished to say, the latter part of the "extract" contradicting the first part.

I am, Sirs, yours faithfully,

London, Jan. 5th, 1892. W. J. MOORE, Surgeon-General.

DISTRIBUTION OF TRACTS IN HOSPITALS.

THE *Philanthropist* for January gives insertion to communications from writers who draw attention to the annoyance caused to some hospital patients by the persistent efforts of well-meaning persons to pester them with tracts and unasked-for religious counsel and admonition. On the whole, we agree with the writers, that such attempts to administer spiritual aid should be seasoned with discretion, and should be made for the most part subject to the request of the sufferer.

Inquirens.—The questions are purely legal, and can only be answered by a solicitor with the document and all the facts before him. Probably, as the matter is involved, the solicitor would have to consult counsel.

Mr. J. R. Catling.—We have no record of the death of the gentleman named.

VULCANITE DENTURES.

To the Editors of THE LANCET.

SIRS,—In the current number of THE LANCET a short article appears pointing out that in some mouths vulcanite is intolerable, though it does not insist upon the theory that it is owing to the oxide of mercury set free that this irritation is set up. I well remember when with Mr. Catlin in London that we had to make a set of teeth for a lady, when the absorption of the alveolar processes was so great that vulcanite was clearly indicated. These teeth were so uncomfortable that they were eased and eased out of all fit, and no less than six sets were made, with like result. Finally, I carved one out of hippopotamus ivory, fitting in teeth in the old-fashioned way, and this set she was able to wear, but during the last twelve months I have had two cases of intolerance of vulcanite, and in both have got over the difficulty by making gold plates. The vulcanite, being a non-conductor, prevents the natural heat of the palate—and in one case the lower jaw also—*from* diffusing, making the mouth disagreeably hot and sore, which metal plates have instantly relieved. Probably the first case might have been successfully treated in a similar manner. Vulcanite is so very useful in many cases, and especially as a cheaper base for artificial teeth, that it is just possible many might be afraid of failure with vulcanite, and, not being able to afford gold, might deny themselves these important aids to digestion. It is, perhaps, kind to let them know that these cases are extremely rare.

I am, *Sirs*, yours truly,

Nottingham, January, 1892. HENRY BLANDY, L.D.S.Edin.

Pathos.—1. The most remarkable essay on "Saline Injections in Cholera" is in Dr. John Mackintosh's "Principles of Pathology and Practice of Physic," pp. 335-371, published in 1836. In the Drummond Hospital, Edinburgh, Dr. Mackintosh treated 156 patients in extreme collapse with saline injection into the veins, using first the saline solution suggested by Stevens (an author—on the blood—of great repute in his day), and afterwards a more successful modification of that solution made as follows:—Chloride of sodium, one ounce; bicarbonate of soda, eight scruples; water, ten pounds. Before injecting the solution the fluid was heated to 166° F., and in extreme cases to 120°. The results were as striking as those in the case recorded by Dr. Richardson, to whose recent paper in THE LANCET our correspondent refers. Twenty-five of Dr. Mackintosh's patients recovered, under this treatment, from what seemed "the very verge of the grave." He took half an hour to inject the ten pounds of liquid. 2. Dr. Richardson's "automatic syringe," manufactured by Krohne and Sesemann, of Duke-street, Manchester-square, is the latest improvement in syringes for the purpose named by our correspondent.

Mr. Chas. Gayford must pass the examinations for the double diploma. Information concerning those examinations will be found in our Students' Number published in September last.

"A SUGGESTION FOR CHRISTMAS."

To the Editors of THE LANCET.

SIRS,—I have only just noticed a letter in THE LANCET of Dec. 19th, headed as above, appealing to members of the profession at home to give surplus instruments and books for the use of medical missionaries abroad. The calls upon the different missionary societies are so heavy that they are not often able to give their medical missionaries a full outfit of instruments, and often cases have to be sent away from the hospitals for lack of the necessary knife or forceps. Plenty of good work is done at these mission hospitals, as your columns from time to time testify. Only last week I heard from one missionary who had performed twenty-seven cataract operations in one week. The Church Missionary Society are very anxious that their medical missionaries should have all that is needful for their work, and I should be very glad to receive on their behalf any gifts in the shape of money, instruments, drugs, appliances, or books which any of your medical brethren may be able to send. Parcels should be sent to me at the Church Missionary House, Salisbury-square, E.C., or I would arrange for their collection in town.

I am, Sirs, yours truly,

HERBERT LANKESTER, M.D.,

Hon. Sec. C.M.S. Med. Mission Auxiliary Committee.

Salisbury-square, Jan. 6th, 1892.

ICE ACCIDENTS.—A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—Each winter furnishes its quota of deaths from accidents on the ice, when many lives are lost through the needful appliances (ropes, planks, ladders, &c.) not being close at hand or obtainable in time to be of any service. My attention has been drawn to the matter by the accident at St. Helens on Dec. 29th, when the ice suddenly gave way, immersing two of the skaters. Their friends quickly attempted to rescue them, when the ice again collapsed, and six more were immersed. By the aid of ropes and planks all were rescued, though one for a time remained unconscious. My suggestion is that each skater wear a strong rope or cord, of four or five yards in length, either as a girdle around the body or as a sash over one shoulder, on which it may be fixed by a loop and button. Such a cord might be made of similar material to the worsted cord of a dressing-gown, with tassels over a cork float attached to the ends, and of various colours, to harmonise with the dress of the wearer. The skater would not find it any impediment to free action. It would be ornamental as well as useful. Two or more of such cords could be quickly tied together by a reef-knot, and the tasselled end either thrown to those struggling in the water, or tied around the body of anyone attempting the rescue, or might be quickly fastened to the end of a ladder or plank, which should always be at hand where numbers congregate to enjoy the exhilarating pastime of skating. Thus such ready, prompt, and efficient aid could be rendered by ambulance pupils and others as would save many a valuable life. I am, Sirs, yours faithfully,

Mytholmroyd, Jan. 5th, 1892. JOHN H. THOMPSON, L.R.C.P.Ed., &c.

A. E. M.—We believe an institution of the kind exists in New Ormond-street, W.C. It is named the Home for Infirm and Invalid Women, and the terms are very moderate.

A. W. H.—Our correspondent had better consult a solicitor. Any claim he might be advised to make would have to be adjudicated on in the County Court.

Nurse.—We are not aware of any such case having been recorded.

GUINEA-WORM IN SCROTAL CYST.

To the Editors of THE LANCET.

SIRS,—As a sequel to the presence of round worms in a cyst, quoted in your issue of Dec. 26th, 1891, on the authority of an Italian contemporary, I should like to mention the following facts.

Whilst Acting Colonial Surgeon in the Colony of the Gambia, West Africa, my attention was drawn to a convict in the gaol, who had a fluid swelling in the neighbourhood of the left testicle. As the skin over it was thinning, I incised it. The contents proved to be a quantity of watery pus, with much flocculent débris suspended in it, and twenty-two inches of a guinea-worm (*Filaria medinensis*). The patient made a rapid and complete recovery, the cavity closing by granulation. As is generally the case with African natives, no history could be obtained. During 1888, 1889, and 1890 I saw but a few instances of this parasite; but those were sufficient to show me that the natives well understood the method of rolling it over a small piece of stick, with a view to its gradual extraction. I never saw the point of emergence higher than the umbilicus. I am, Sirs, yours faithfully,

Devonshire Club, S.W., Jan. 5th, 1892. PERCY RENDALL, M.D.

A Surgeon would not, we think, be justified in using any remedy the nature of which was not known.

A. W. S.—Certainly; or we shall be glad to receive Dr. Jacob's own description of the distoma.

B. L. T.—The grants, like the rest of the profits, should be equally divided.

Fritz should consult his medical attendant.

INCOME-TAX ASSESSMENT.

To the Editors of THE LANCET.

SIRS,—The matter upon which "Marylebone" has written to you is not a very important one, as should insurance premiums not have been deducted from the assessment, the tax thereon can be claimed at any time within three years following the expiration of the year of assessment. But what is important is that where profits for the year ending previously to April 5th, 1891, have not reached the amount of the assessment upon which income-tax was paid, notice should be given at once to the surveyor of taxes so as to enable the taxpayer to obtain relief and refund of tax. The time for making this claim is strictly limited, and the claim can only be made for one year.

We are, Sirs, yours faithfully,

A. CHAPMAN & Co.

Income Tax Repayment Agency, 25, Colville-terrace, London, W.

ARTIFICIAL TEETH FROM A SANITARY POINT OF VIEW.

To the Editors of THE LANCET.

SIRS,—*Apropos* of your article in THE LANCET of Jan. 2nd, allow me to mention that a lotion composed of equal parts of dilute hydrochloric acid and water, applied about once a week with a dental plate brush, is very efficacious as a purifier of false teeth.

I am, Sirs, yours faithfully,

HENRY SUTHERLAND, M.D.

Richmond-terrace, S.W., January, 1892.

The Publisher cannot hold himself responsible for the return of testimonials &c. sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

The Harveian Lectures
ON
COMMON NEUROSES, OR THE NEUROTIC ELEMENT IN DISEASE AND ITS RATIONAL TREATMENT.

Delivered before the Harveian Society of London, Nov. 19th and 26th and Dec. 2nd, 1891.

BY JAMES F. GOODHART, M.D., F.R.C.P.,
PHYSICIAN TO GUY'S HOSPITAL.

LECTURE I.

GENTLEMEN,—When your President and Council did me the honour to invite me to fill for this year the post of your Lecturer, I accepted with no more than the momentary hesitation that might be the natural physiological reaction of any surprise. And I did so because the reflection of a moment made it clear that the request came, not to *me* personally, so much as to one of the physicians, and therefore to one of the accredited mouthpieces, for the time being, of Guy's Hospital. To have declined such an invitation, however much private inclination so counselled, would have been to run away from an obvious duty, and to cast a slur upon an institution that deserved nothing of that sort at my hands. So I am here to-night relying on, and attempting to personify as best I may, my nursing mother; dear to me, as those other kindred and not less noble institutions where you severally have studied, and spent, it may be, the freshest years of your lives, are dear to you, my hearers. But having thus somewhat impulsively taken up what seemed to be a duty, I am free to confess that it was a case of "marry in haste and repent at leisure," for only when there was no escape did I realise that a matrimonial project of this sort was not to be "enterprised nor taken in hand lightly," and anxiously did my mind range the wide field of medicine for some subject that might prove not only instructive, but also attractive, at this somewhat somnolent evening hour. Ruskin has said in effect, in his "Sesame and Lilies," that in reading a book one should try to get at the author's meaning, rather than let him be interpreted by the light of our own thought. For the poet, the mystic, the moralist, I might allow this to be true, though I am by no means sure that it is so; for the books that have most taken hold of mankind have ever been those in which the author has dealt with subjects for which no language could be precise enough; and that hold has been gained not necessarily by beauty of language, though that has often been conspicuous; not by wealth of idea, though that may have been abounding—but chiefly, as I believe, because individual minds of the most varied type and depth of intelligence have each and all, in attempting to unravel the writer's meaning, unconsciously, it may be, seen in it their own experience, and interpreted it on these lines. Do you believe, by putting Shakespeare on any pinnacle of intellectual acquirement you may please, that any single brain ever had within its compass the half of the ideas that have been found by others in his plays? I believe that if we could piece together all the knowledge that from then till now has been supposed to have been put into his work, of his own purpose and intention, we should build up an individual who even at this advanced period of the nation's history would be a psychological impossibility. Shakespeare is Shakespeare, Milton is Milton, Browning is and will be Browning if you like, it matters not whom of the greatest writers of the past we take, each and all of them, great as they were and are, would yet be comparatively unknown to fame were it not that, in attempting to interpret them, age after age has interpreted itself through them. I question whether it could be otherwise. It is the natural resurrection that a great mind may expect. But let this pass. If what Ruskin says be true for the writers of books, it is hardly so for the audience of a lecturer on medicine, and I seemed to receive *my* mandate from quite another point of view, and from a very different source.

Those of you who have read "Life's Handicap," by Mr. Rudyard Kipling, will remember that in the preface—to my mind the most charming part of the volume—there is a dialogue between an old Indian of eighty years, Gobind the one-eyed, and the author, with reference to the art of telling tales. There are one or two passages in that preface, by-the-bye, that seem to bear upon medical authorship. For instance: "I write," says the author, "of all matters that lie within my understanding, and of many that do not. But chiefly I write of life and death, and men and women, according to the measure of my ability. Then, by the favour of God, the tales are sold, and money accrues to me that I may keep alive." But with more special reference to the work before me he asks, "'In what manner is it best to set about the task, oh chiefest of those who string pearls with their tongue!' 'How do I know?' said Gobind. 'Yet,' he thought for a little, 'how should I not know? Do thou this: tell them first of those things that *thou* hast seen and *they* have seen together. Thus will their knowledge piece out thy imperfections.'" And this is what I have ever found the readiest way to my hearers' attention. This is what I shall now attempt to do. I propose to give you a plain tale of my own experience, feeling sure that in so doing I shall appeal to similar experiences of your own, and I hope that the piecing-out process may prevent the time from being altogether lost. Thinking thus it was that I determined to deal with the subject of neurotic conditions, and here it was that I came across my first difficulty—the question of a title to these lectures. All titles and definitions bind one, and I want to present the neurotic element in disease to you as it has presented itself to me, and that presentation does not well allow of any than the most general definition. "Neurasthenia" would, I think, have been the most fitting term, but that in inviting you to listen to lectures comprehended by that name I feared to seem to limit your vision to massage and stuffing, which I have no wish to do. Included within my horizon are such diseases as asthma and angina pectoris, and indeed the subject is all too wide. The common neuroses of modern life next came to my mind, but some of my friends said that a title of that kind was rather too suggestive of a ticket for the play. So at last the heading stands as it does, and if it be somewhat vague, I at any rate feel that I have a free hand.

But modern life is, after all, my chief theme; and insistance upon it is one of the first points that I wish to make, for it is the very mainspring of my subject; or rather, I ought to say, of my idea of it. As year succeeds to year of life I become more impressed with the widely prevailing influence of the neurotic element in the production and carriage of disease. And it is my own opinion that it is largely more so than in former years. I shall not attempt to prove this, for I feel confident that figures could be made to do service either way according to the bias of the manipulator. I therefore simply give it as my opinion, worth no more, but worth no less, than that of any other individual who has had an equal opportunity of observing. For let me remind you, the conclusion that I had come to has determined the subject of these lectures; it was not formed after I had settled that question. If I look through my notes of cases that I have seen there is no group so large as that of the neurotic in one form or another, and I really do not think I have exaggerated this feature. I believe that insanity is on the increase; but I refuse to be confined, in speaking of mental disease, to those grosser forms that require to be committed to the hospitals set apart for such cases. Incidentally I may say too that I believe that the grit of the English constitution has lessened in robustness; and if the question—Why, then, is the average duration of life longer?—seems at first all too pertinent for the maintenance of that contention, a very little reflection will convince anyone that no great weight attaches to it; for in both cases—physical and mental death to bring both cases at once into the same line—it is more than probable that the last extremity is averted by our greater care of life at the present day, and that the average is lengthened out by the large prevention of preventable diseases. Yet men and women may drag along more self-conscious, more oppressed and weighed down by trivial ailment; less ready to step out with the spontaneity and joyous liberty and power of healthy life, so that if one man might say that to-day there is less of capital punishment there are ten men who would make answer: Even so! but there is more of penal servitude and of the treadmill.

I remember five-and-twenty years ago, when first entering

Digitized by Google

the medical profession, that some one, I think the late Sir Thomas Watson, had given expression in public to the opinion that disease had changed its type. I was surprised to see, even at that early date of my career, how much discussion that opinion excited, and even more surprised when, after a time, it was practically recanted. I thought then, and I think still, that unless the world is standing still, disease *must* change its type, that it has changed its type, and is changing it. Some of you at any rate will remember that the discussion had already turned around the former treatment of pneumonia by bleeding and its then and present management without. And, surely, the argument in favour of a change of type on that ground was not wanting in strength. Still, I would maintain that it was not the strongest upon which the contention could be supported, for it was quite open for those who had years enough to say that the pneumonia of a former generation was in all essential features the pneumonia as we know it now, and that was indeed the line taken, and many supposed successfully so. But a quarter of a century has gone by, and almost within that time the doctrine of evolution has come into existence and has grown into robust manhood. In those days change of type conjured up the idea of kangaroo jumps from the disease of one day to that of some successive one. We can understand now, if we could not at first sight then, that no such demonstration is possible, because it is out of the natural order of things. But the absence of gross changes within the span of a century or two does not touch the assertion that disease has changed and is changing. The changes that occur are subtle and gradual—as gradual as those by which man himself must be changing, because this earth is changing, and unless he accommodates himself to his altering circumstances the man of to-day will have to make way for some other being more pliable than he. I see no escape from the absolute certainty of the conclusion based on this *a priori* consideration that disease is changing, and changing, too, in all sorts of directions in correspondence with the manifold modifying circumstances to which it is subjected. I need hardly give any illustrations of this, they are so abounding; but to show the intricacy of the case let me insist on this maxim—"No man liveth to himself, and no man dieth to himself." Apply the principle, for it is a principle, to the exanthemata; and to what we are doing in all directions both preventive and curative at the present day. It is impossible, I take it, to do away with one of these scourges or to render its reaction on the human body less severe, without the change or changes reacting to a wide extent, and probably far wider than we have any idea of, upon a number of other processes of disease which they involve in their unbridled turmoil. For instance—and there could not be a better one considering my subject,—there is many and many a home now bewailing the ravages of disease in one or other of its members relighted, or may be *started*, by quite another disease,—viz., that interesting pest influenza! I suppose there is not one of us who does not see even now almost every day some case or other that dates its initiation from that disease of now wellnigh two years ago. I think it would be difficult to say in how many ways that disease has attacked the human organism and laid it open to attack, or in how many directions its absolute extirpation would better the future of the race. I take it, therefore, that disease is changing its type not only in accordance with the changing circumstances of man and his surroundings, but also in accordance with the modifications that are produced in it in its various phases, as each or any of them are made to submit to the assaults of advancing knowledge.

However this may be, my chief point now is that man himself is changing, and if so, so must his diseases be, and I believe him to be changing chiefly as regards his nervous centres, and that these are becoming more prone to fatigue, more easily the prey of morbid sensations, of morbid thoughts, of morbid action, and so on. But I am not sure that this is so, at any rate equally so, in all the strata of society. I do not think that it is, and my own experience goes strongly to show that the stress of living tells largely against the middle classes of our world. "Liberté, égalité, fraternité" is the prevailing cry of the day; we are all men and brothers, and a savage is as good as the most cultivated man. This may be good sociology or political economy, but it is not sound physiology. There can be nothing more sure in physiology than this, that, as we go upwards in the scale of creation, so the nervous system becomes more sensitive to pain and to disturbing sensations of all sorts. There can be no doubt that operations can be performed on the lower animals without any of the precautions that are taken in the case of ourselves, and that the results are astonishingly good all the same. I think there can also be no doubt—one has seen illustrations of it so often in the out-patient room and elsewhere—that the differences that are seen in this respect between the lower animals and man are seen in a similar, if less marked, way between the lower and upper grades of society. Who does not remember to have seen, and even often seen, patients in the hospital out-patient room, desperately ill and even within a very few hours of death, yet hardly allowing that there can be anything serious the matter? I remember, too, to have seen more than once a man come to the out-patient room for some ailment confessing to nothing else than that for which he had applied, and yet on being overhauled he is found to be the unhappy possessor of some huge ulcer of the leg that would certainly have quite incapacitated anyone in the upper walks of life, but which he called "nothing." It is said that the working man cannot afford to lie up, and therefore he does not call attention to things that are chiefly an inconvenience. But this is no adequate explanation; to my mind, this would not explain the power he possesses of working under such very adverse circumstances. I feel sure that the reason is none such as this, but that it springs from the fact that the working man is generally far less sensitive to depressing conditions than those above him in the social scale; his nervous system is far less sensitive. We see the same thing in the difference in the reaction to drugs that may be seen at the two levels. Give belladonna and nux vomica with an equally free hand to the hospital patient and to the delicate lady, and we soon see the difference. It seems obvious that the one who has had to rough it has become deadened to trivial shocks of all kinds; while the other, pampered in the lap of luxury, has become cultivated into such a state of nervous erythism that the least disturbance upsets her. But more than this. Not only does the neurotic state evolve more, as I think, in one stratum of society than in others—it has its lines of special development in some occupations more than others. I wish there were time to develop this subject, for it strikes me as an important one. I have in mind the neurotic tendency as it shows itself in the clergy, in those whose occupation is to deal in stocks, in those whose occupation is our own. But interesting as this line of observation is, I must confine myself to saying that, for the most part, the clerical neurotic is irritating to others rather than dangerous to himself; the dealing in stocks seems to me to be liable to produce a state of nervous instability, such as would seem to threaten an ending in insanity of some form or other, of the frequency of which I should like to hear something from those who by their practice are more familiar with the professions as they are found in asylums than I am; and of the medical neurotic—well, I am not bound to say anything of my own cloth, so I shall leave him to your kindly judgment, more particularly as he is generally youthful and inexperienced. It is my conviction, then, forced upon me by the experience of now many years, that the maladies which owe their origin to a faulty action of the nervous system are of more frequent occurrence in practice than are even phthisis, heart disease, Bright's disease, or organic hepatic disease, though these are in no small number.

Now, as time goes on and the subject develops some will certainly raise the criticism that the seeing this element in disease largely depends upon the standpoint or the bias of the individual observer, and I shall admit this risk, but to that I shall address myself as I take up particular subjects, more particularly the treatment of the neurotic affections of the stomach. To these particular maladies we must now proceed, and I propose to divide the subject into the following groups: The common neurotic conditions which may be said to be essentially central in their whole course; those that are pulmonary; those that are cardiac and circulatory; and those that are abdominal, concerning themselves with the stomach and bowel and liver and kidney. Of those that are central it is difficult, if not impossible, to give any adequate clinical description, because concerning themselves as they do so much with subjective sensations, they are as various as the variable mental conditions of the individuals in whom they occur. But nevertheless there are certain common methods of disturbance of the healthy cerebral action; and first of these I will mention the curious

Digitized by Google

dread that some neurotics have of going into society or into any crowded place. Ladies will come and tell you frequently that they cannot go to church because they are afraid that they will faint or that an attack of what they have generally agreed to call the fidgets will come on, and that they will have to go out. I have known this dread to take possession of men, but in them it is perhaps more often a modification of the same thing—viz., a dread or at first a disinclination to go out and see their friends, which, if it be indulged in, becomes before long an "all-overishness" at going into society of any kind that quickly converts a man into a recluse. In women there is another common phase of the same malady—viz., where the subject describes herself as turning scarlet all over. Some inborn sensation starts what is usually described as some sudden rush of blood upwards, and thus they usually describe themselves as turning colour, although I do not think that they often do. The hot sensation is succeeded by a copious perspiration, and of this sweating there can be no doubt, for I have been repeatedly told by the subjects of such attacks that their underclothing becomes quite wet.

This is a short description, but I think it embraces all the essentials of a large, very large group of cases. Now, how are they usually treated? How are they to be treated? The general plan of dealing with them is, I think, to call them hysterical, and to administer assafœtida and valerianate of ammonia. I have nothing to say against these excellent remedies; they are very good in their way, and I am not prepared to say they are not the best in these cases; but there is a right way and a wrong way of administering even proper remedies, and to offer either as a *cure*, is not the proper way of dealing with any such case as I have depicted. If we should have to do with a frightened horse that will not pass a certain spot, we do not send him to the veterinary surgeon that a bolus may be administered, but he is walked up and down before the object that disturbs him until his self-possession is regained, and he finds that what startled him is, after all, nothing to be alarmed at. So must our patients treat themselves. Their nervous systems revert to a similar state of unreason as that seen in the startled animal, and the only way to cure them is to restore their confidence in themselves. Something may be done by good nerve tonics, sometimes by sedatives judiciously given, to help them to help themselves, but clearly the only way by which they will overcome their weakness is by becoming oblivious to the conditions that are the cause of the self-consciousness and distrust. For instance, in the common dread of doing something foolish or coming over ill in church or society, the difficulty is usually surmounted by staying away, and I say that to deal with it thus is to encourage the malady. The true method is to go and do all that comes to the hand to do, and thus to learn again, that what had been thought impossible, without a catastrophe, is accomplished without any ill result. It is constantly impressed upon us that all this has been done, and without avail; that the patient has struggled against the feeling and has been unable to overcome it, and this is supposed to be an argument against the advice that has been given. But it is nothing of the sort. There are hundreds of neurotics who fight and struggle and try not to give in, who are really consuming themselves in the bearing, and who are all the time by so doing kindling the flame of their neurosis by encouraging their self-consciousness. Surely this was so in a young lady I saw the other day, whose mother remarked to me that her daughter was the most absolutely enduring creature that was ever known. This lady little knew my inward response; that she who goes about the house with sweet resignation set upon her face is ofttimes one of the most incorrigible of neurotics. A neurosis is best treated by the cold shade of neglect. Moreover, to struggle against a feeling you cannot help, and to call yourself hard names for being overcome by a distressing feeling that was none of your own invitation, is equivalent to flogging the frightened horse, and the result in both cases is the same—the state of panic is made worse. The best way of meeting these ailments is to allow to the full the misery that they cause to the individual, but in doing so to insist (1) that they are always transitory, (2) that they are purely subjective and not perceptible to others, and (3) that they never do any real harm or mean any organic disease. As I have said, unconcern at their approach and during their course is the certain cure; but, alas! I must add, even so, that the remedy is easy to preach but difficult to put into practice. Remember, though, that this difficulty does not alter the certainty of the facts.

Next there comes a large group of cases where the morbid sensation is chiefly confined to the head; there is either headache or a clawing inside the head. Some will say their brains feel as if their top storeys were converted into wool; others, again, suffer from what, according to their own descriptions, appears to be a species of mild explosion sensation within the skull; and then there is the very large group of cases that come for noises in the ears. It is perhaps seldom that one sees a typical case of Ménière's disease, but regarding Ménière's description of auditory vertigo, as I do, as a *type*, in the same way as I shall by-and-bye insist that Raynaud's disease and exophthalmic goitre are also of a large group of symptoms, the tinnitus aurium and deafness form the very commonest of the neurotic ailments which come before the physician in his daily work. But someone will perhaps say, Why call this a neurosis? It is a definite affection due to irritative or destructive lesion in the semicircular canals. So it may be, but I am none the less very much concerned to insist that the disease as I know it is very seldom, indeed, if at all, a simply local disease, and it is nearly always found in those of markedly neurotic constitution, either of themselves, or more often, I think, as regards their family history. For instance, this case comes before me: A lady of my acquaintance suffered for years from noises in her ears, which could only feebly be kept in the background of her mental activity by constantly keeping a musical box going. What was her family history? Her brother was in an asylum for some years before his death; another member of the family suffered from harmless delusions, and passed into a state of senile imbecility out of proportion to his years. And this does not tell the half of the neurotic strain in that family, for beyond the gross departures such as these there runs through all the members an indescribable eccentricity such as cannot be put on paper, but which is nevertheless very real and obvious to those with whom they come in contact. Here is another case of a gentleman of sixty-three years who was under Sir William Gull many years "for the nerves of his head." He says that his mother suffered greatly from "bile," and was always under the doctor; a history that I shall by-and-bye contend shows a vice of the nervous system! He has had good health, but every now and again, with complete freedom between the paroxysms, there will come a roaring in his head which he describes as a mill stream going inside him, and he staggers about as if he had been drinking, and he will also occasionally see double.

In another case you only want to look at the man to see that he is liable to nerve-storms of all sorts, for his head goes almost to a point at the forehead, and his whole history is that of a highly neurotic man. He is all right away from business, which is a large one, and in which he has much to do with figures. He had been to an authority, who told him he had a weak heart, which nearly finished him with fright. He appears to have rebounded in consequence into the chair of an ear doctor, who told him he had Ménière's disease, and I suppose that, finding himself between the devil and the deep sea, he came to me for consolation, which I gave him. Once more, as showing that these cases form a large group and have relations with other neurotic states, I note the case of a man of fifty-four, in whom in association with the noises in the head and ears there come on from time to time attacks of faintness, in which he flushes up, his veins stand out, he gets a little giddy, and he breaks out into a profuse perspiration, his account being quite like that of the woman so much more commonly seen with flushings to whom I have already alluded. The attacks in this man, although one cannot but think from his whole demeanour that they are subjective entirely, are nevertheless clearly very real, for they compel him to sit down wherever he may be until they have passed off. Of twenty of these cases taken from my note-books one only had evidence of local ear disease, and all were people whom I should call very nervous. I may also note in favour of a central origin that these symptoms certainly in the large majority of cases are paroxysmal in their occurrence at the onset, and may remain more or less so to the end, for many people will tell you that they get better or worse according as their general health is better; but the tinnitus very generally tends to become confirmed into persistency as years go on. Again, as pointing in the same way, according to my experience there are two classes of cases, the one that makes no more than an inconvenience of the malady; and in these, although it is a serious and, indeed, a dis-

Digitized by Google

tressing affection, it does no harm; in the other it is ever present, is nursed, so to speak, and brooded over, and day by day a greater degree of mental wretchedness is produced, until, if not actually insane, the sufferer becomes very much of a mental wreck.

This leads me on to a somewhat different condition, but as regards results a closely allied one—I mean insomnia. Now what is sleeplessness? I have in former years described it as a bad habit of the nervous system, and so it is in most cases; but it is also more, for if we go into the history of this trouble we almost always find that it can be traced back to parental tendencies in the same direction, while it is also one of the commonest forms of the manifestation of nervous fatigue and breakdown. There is therefore ample evidence for regarding it as a vice of the nervous centres. Yet I hold that it is a vice that is too often detrimental to the patient simply because of an inability to rise above it. It is very much with the sleepless as it is with the subjects of Ménière's disease; for if we look at the subject from a physiological point of view there is nothing so very harmful in sleeplessness. There are plenty of people going about who sleep no more than three or four hours; there are many more who are the lightest of sleepers, which means that they wake many times in the course of the night; and those of either class would not dream of considering themselves out of health. They go about and take little heed of what is really not the normal state of things. They take their sleep in snatches, like the heart, and do fairly well upon it. But as soon as we get it on the brain that the sleeplessness is a serious matter, that it indicates serious nervous weakness, and that it will end sooner or later in insanity, then it becomes a very serious thing indeed. Then it is that it does become a dread, and every returning night becomes a hot iron entering into the soul, for it is met with the closed teeth of an expectation that will certainly be fulfilled. It is thus I think that the patient tosses about and arises in the morning in such a dilapidated condition. "I am sleepless, I am sleepless" is the night-long refrain; whereas a dominant thought of this kind should be neutralised by its antagonistic one: "This is very unpleasant, but what does it matter?"

I pass naturally from such subjects as these to others that are still more purely of mental origin. There are many of these that give much anxiety to individuals, and for which they come to the physician to be reassured. A large number come because they are losing their memory, or think they are; others come because, comparing themselves with some others of their acquaintance, they think they cannot do such and such things as well as their wont was, or as well as they. Others, again, there are who have time-honoured fits of the blues, and very curious is the persistency of the idea with which the patient is ofttimes possessed. One of the more recent cases that have come before me was a young man who, although he had been assured that there was nothing the matter with him—that is to say, no organic disease,—and although he professed to have a thorough belief in his doctor, nevertheless came for another opinion, because he was certain that there *must* be something the matter because he perspired so much. I talked to him for some time and carefully went over all his organs, just to satisfy him that everything had been done to make certain that there was no disease. But I feel sure that I made little real impression upon his mental condition, for it is the habit of these patients to be a little more cheerful while they are talking to the doctor, but to speedily relapse as soon as the sound of his voice has passed away. Of other common complaints I have jotted down these: headache, pains in the back of the head and dreadful depression at the top of the head, a sensation of going out of one's mind, inability to concentrate thought, fits of absent-mindedness, clouds of depression and sleeplessness. Pins and needles and numbness claim another large group of victims who die daily in imagination of paralysis; others come because their hands shake, others for fainting fits, others for a feeble circulation. Another group is formed by people who come and tell you that they are hardly ever free from pain. There is an instinctive dislike in most of us, when a person complains of pain, to say there is no disease; and it is necessary in such cases to be very careful that we do not let an idea run away with us. Nevertheless, I think that it must be admitted that there are a fair number of people who are always in pain, and who yet have no disease. I have several times had people make this complaint to me, and I have come to the conclusion that there are some people in whom the ordinary processes of life are conducted with pain, and yet without organic disease. A large number of such seem to affect uterine disease, and find their way into the hands of the gynæcologist; some as having ovaries, others as having flexions, others as having a general lassitude and dull dragging backache, and other ill-defined pains about the pelvis and lower extremities. Another large group affect spines, and lie on their backs for months, and lead their friends and their doctor a fine dance, unless some dire necessity steps in, and, by taking them out of themselves, changes the current of their lives. It may seem hard to say that such people must learn to bear their pain, but so it is. Herein is one of the mysteries of pain—there is no standard by which to gauge it. In the abstract it is part of the common lot of man, but there is nothing that is less common between you and me. What is agony to you may be a mere fleabite to me; and it is obvious, I think, as indeed I have already indicated, that in its higher refinements it is a product or development that marches with the march of the keen nervous susceptibilities of modern life. I cannot believe that pain plays upon the same number of strings in the lower animals as it does in man; I cannot believe that pain conveys the same sense of suffering to the savages of equatorial Africa as it does to our country labourer; I doubt if pain is the same to the country labourer as it is to the working-class toilers in our large industrial centres; I cannot believe it is the same to these as it is to the higher grades of society. And if there are these differences, as I think there must be, so there must be differences between individuals, and inasmuch as I can only judge of your suffering under given conditions by what I have felt myself under such circumstances as happen to have been most similar, we have no common ground, or next to none, and we must therefore deal with pain in the main upon Nature's great principle of strength sufficient for the day. We talk of *treating* pain; but if we think about it, how large a part of physical pain, and all the greater pain of mental anguish, has to be borne. And if this indeed be Nature's law, as it appears to be, that the larger part by far of the sum of human pain is thus without remedy, there can be no unkindness in anyone if he should say that the best cure for many a lesser pain is to learn to bear it. And so it is. The very effort is a tonic with which no drug in the pharmacopœia can, all round, compare; while every potion is a submission to circumstances which, when the next call comes, will necessitate a stronger dose. "The weaker a body is the more it commands; the stronger it is, the more it obeys." I am afraid I am hardly making my meaning clear, but it is this: that pain is, after all, only one form of morbid sensation. I am not sure that it can rightly be called morbid in many cases seeing that it is so often but the fag-end of pleasure. Why, then, should we fly at once to deaden pain by opiates and sedatives any more than we should apply to the same source to relieve some other unusual sensation, such as, for instance, some slight itching of the skin? An intolerable itching we should all agree to try to stop, because it is out of the common, and when controlled one may hope, or even confidently expect, that it will not reappear; but a slight irritation of the skin is so much the lot of all at one time or another that we take it as one of the daily vicissitudes of life. Why do we deal with the slighter forms of pain, as, with some exceptions, I think we are too much in the habit of doing, in a different way? I believe the reason to be that which I have given—that we have no gauge for the degree of pain, and because the advice to grin and bear it is too likely to be resented, unless it be presented with tactful modulations, the power of which we do not all possess. The truth of what I am saying is illustrated well by perhaps the most homely ache that we possess—viz., toothache. He would be a very unwise physician who for every aching tooth advised extraction, because we all know well that a bad tooth will often ache as a barometer of fatigue or worry or ill-health. A dose of quinine, a dose of rest or sleep, sends many an ache of this sort away; while I suppose you must all remember similar cases to the neurotic lady I saw the other day, who, refusing to accept advice and wait for the action of such remedies as these, insisted on having her tooth out, and then came back to me with her ache far worse than it was before.

Now whatever may be the common practice with each of us, it is quite certain that such cases as I have mentioned

Digitized by Google

of general aches and pains are made worse by treatment directed only to relieving their pain or abnormal sensations. I will go further, and say are certainly ruined by such treatment, and they are as certainly relieved somewhat, we cannot say by half as much as we could wish oftentimes, because their ailment is the result, one might almost say a part, of their being by other measures. Job's comfort this some will surely say, but I reply that to recognise the reason of a thing is always the first step towards any real cure. And let me enforce my remarks on this head, and perhaps help to make my meaning still clearer, by alluding to another common group of cases. There came into my room one day a year or two ago, on one of the hottest of summer days, a young Cambridge graduate, of whom I had previously heard that he was a martyr to his ill-health. From what had been told to me I was not altogether surprised when a dark-haired, pale-faced, nervous man appeared upon the scene, cloaked in a thick inverness cape and with his collar turned up. But I was surprised, when peering slowly round the room, he espied a window open by a hair's breadth, and immediately asked leave to shut it. This in the middle of summer, mind you. My wonder grew, too, apace as he next proceeded to divest himself of layer after layer of apparel; first his inverness, next his coat, then, I think, more than one waistcoat, a linen shirt, a flannel shirt, a Jaeger, and last of all a chest protector. Can you wonder that he had developed a subserviency to what he was pleased to call draughts and chills, that made his life not worth the living? This poor fellow was leading a wasted life, for he had given up, or deemed himself unfit for, the occupation he had wished, and why? Because, so far as I could find out, he had been nursing his neurotic tendency until he had become a perplexing and anxious burden to himself and his friends. A straight talk on the elements of physiological knowledge came as a revelation to him; so much so that I was enabled to induce him to leave my room without his cape on, though how soon he went further than that I have not been privileged to know. But, at any rate, I hear that not long after seeing me he went to the tropics; has lost all his weakness, and become quite a new man. He is now married, and rushes about, and does anything like an ordinary mortal. But the main point is, How came he to this pass? And I hope I shall not be considered uncharitable in attributing something of the bad result to a want of vigour in the professional advice he had been receiving all these years. We are many of us much too afraid of giving advice to patients that we think they will not like; and in being so, a poor neurotic slides on, year after year, and, only too likely, becomes eventually a wreck at the hands of the profession which should have saved him. And if you doubt it, think only for a minute of the many women who are only too ready to think they have a spine. There is a halo of sanctity attaching to the spine, such as never has been thought of for the skull; and I really believe there are some who regard a weak spine as an evidence of distinction, they nurse it so long, and even in after years still seem to regard its former achings with such affectionate, if not regretful, tenderness. Well, now, I doubt whether there be such a disease as neuralgia of the spine; but no doubt the difficulty lies in distinguishing between the early stages of spinal disease and the mere achiness that is best treated not by rest but by distraction. This must be so, for I could show you a man now who has been cauterised all down the spine, who has had a running sore made and kept open for weeks, who has been roaming the wide world under "the best medical advice," but who has never had a whit the matter with him save a bad set of nerves, and who has been practically well since I told him so.

The next condition that requires mention is a very common one, and I can describe it no otherwise than as simple fatigue. This is of course a vague sort of symptom likely to lead for that very reason to important errors in diagnosis. I feel constrained to dwell upon it because there is no other class of ailments that I find more difficult to make the public understand than this. "I am always so tired," say these men and women, but more often the latter than the former. "I am tired when I get up in the morning, and tired all day, and yet I cannot say that there is anything the matter." Nor is there. "It is better," says the autocrat of the breakfast-table, "to lose a pint of blood from your veins than to have a nerve tapped. Nobody measures your nerve force as it runs away." I suppose that anyone here could give notes of several such cases—people easily knocked up, and yet without any discoverable disease. In such cases it behoves us of course to be very careful not to overlook anything, and it is as well to give several examinations if there be any doubt; but they pursue the even tenour of their languid way too long for serious disease, and the feeling of fatigue is part of the order of their being. These cases all have this other feature in common, that they are neurotics. Let me note the salient features of two or three of such cases. One is a man aged forty-four. He has had rheumatic fever, which in itself is enough to constitute a man a neurotic, for its whole history betokens its affinities. He was in business, but gave that up, and now is a farmer, but he cannot work long. He is not short of breath, and his appetite is as good as ever it was; but he is always tired, and he says he could not walk the ten minutes to his farm if he were given five pounds to do it. In another case it is a woman, again with a history of rheumatic fever, but with no disease. She is a lady of a decidedly intellectual turn, but she declares that she never has any energy for anything, and her daily duties in her house are a regular burden to her. Another case is a young lawyer whose father's family he calls a decidedly nervous one, and his mother is very gouty. He has had indigestion and a liver for twenty years, and wakes up with a coated tongue (I wonder who wakes up with a clean one?). Of late he had lived in the country and had had a lot of exercise, and had been better, but then he got the influenza, and since then he had felt weak. He came to me because, as he expressed it, he was so dead tired from the time he got up in the morning till the time he went to bed at night. He was quite free from disease as far as I could make out, he was not wasting, and I attributed all his ailment to the fact that he was hard at work from nine till six, that all his vital energy was thus consumed, and he had none to give to his muscular system. Now I hope I shall not be understood to say that all those who complain of fatigue and inability to do their ordinary day's work are neurotic. There are of course many causes of muscular fatigue; the man who habitually eats and drinks too much may feel the same lassitude, the habitually constipated the same, the man with an excess of uric acid in his blood the same; but, deducting these and all other causes of muscular malnutrition, such as acute blood poisoning and the like, I will still maintain that there are a large number of people who come complaining of this symptom for which the most probable explanation is that their nervous flow is not produced in sufficient quantity to suffice for the needs of the various organs that require it. There are some who generate enough, but they distribute it unequally, or, rather, the consumption by certain organs is prodigal. The brain holds debenture stock of this investment, and so those who tax their brains unduly, whether by work or worry, are very likely to experience this feeling of fatigue, because their muscular system has not the requisite supply of energy wherewith to make it go. On the other hand, there are others who make little nerve force at the best of times, and although their brain power never shows above mediocrity, or something lower, they yet suffer in the same way as those more highly endowed, but at an altogether lower pressure along the whole line. I shall have to utilise, and I think enforce, this explanation, when I come to the subject of indigestion; but in the meantime I may gain some support for it from another set of cases perhaps similar and only more pronounced, and of which some of you must have seen examples. I mean the curious conditions of complete nervous collapse seen now and again after severe mental strain. Here is such a case. A clergyman aged forty-six, the incumbent of a London parish, first began to have peculiar attacks some three or four years ago after very hard work. He would be suddenly seized with numbness in his hands, his nose, tongue, and mouth, with violent pains in his knees, a feeling as if he were going to die; then a violent fit of crying would come on, and this was succeeded by a sleep of eight or ten hours. He had been well for many months, and, indeed, till just before I saw him, when he had a sudden return of not quite similar attacks, in which *breathlessness* was the chief symptom; but he also had the most acute pain in the right arm, and fainting afterwards, he thinks, from sheer pain. I saw him two or three times, and could not make out much. I never was quite clear about the nature of the attacks; no medical man saw them, and I was therefore obliged to take the statement of the

Digitized by Google

patient and of his wife; and the latter described them to me as a mixture of cramp and hysteria, but that they ended in a state of complete exhaustion and drowsiness, and he only slowly regained his strength. I thought at one time that they might have an epileptic taint about them, but I do not now think that such was the case.

Another case was that of a younger man who had always been subject to headaches, which had of late been on the increase. He had had a great deal of worry before the attack I am about to relate, and, his headaches being worse, he was taking a few days' holiday. When out for a ride he suddenly became quite dazed; he found his way home, or his horse took him, for he was not conscious of where he was, and his memory for that period was a complete blank. He slowly came to himself, but was confused till the next day, and when I saw him so late as six days afterwards he still felt stupid and his head heavy. Except for his headaches he has remained well ever since.

Another somewhat different case is as follows. A surveyor of thirty-six years, whose father died of diabetes, while out with the Volunteers one day in August had a sunstroke. In passing I may remark that a sunstroke must be a serious thing, quite apart from the causing hyperpyrexia, for I have seen certainly five or six cases where it seemed to be the starting point of a number of morbid nervous actions. He had never been well since the sunstroke, he had had vertigo since then and curious sensations at the back of the head. Not long afterwards he fell some twelve feet through a trap-door, and this greatly prostrated him. I could make out nothing except that he had a slight buzzing noise in his ears; but he spoke slowly and in a depressed manner, and all his reflexes, knee and wrist, were exaggerated; and his urine contained sugar in small quantity.

Last of all of this class of cases I would take that of the woman whose attack may begin in a variety of ways, either by an attack of colic or seeming colic, or by violent pain in the side that is referred to the heart, but in all probability not correctly so, or, it may be, by some indescribable feeling of illness; but each and all of these are followed by what can only be described as a state of complete exhaustion. Often have I been called to such cases, and found that the medical man in attendance has been sitting with the patient for hours, perhaps all the night, because he was afraid of sudden dissolution, and the heart is the organ that is supposed to be failing; whereas the truth of the matter is that the heart is perfectly sound, and if one may venture to form an opinion after the crisis is over, I do not suppose there has at any time in the progress of the attack been any danger of death whatever. I cannot think that this is a form of neurosis that receives adequate recognition; and I believe the real nature of the malady is often overlooked because the household is in a panic, thinking the trouble one of the heart, and the medical man not quite sure that there may not be some real disease, and not wanting to make a mistake, first for the sake of his patient, and next for his own reputation, acts on the side of caution. There is no danger in these cases; they only need, they and the friends, who generally cause most of the mischief, a decided assurance by the doctor in a tone that shows to them that he knows what he is talking about, that the patient will soon be all right. A little valerianate of ammonia or bromide of ammonium and sal volatile complete the cure.

One other group of this sort I must mention, although it has been so often talked about that there is no need to say much. It comprises the large group of cases born of anxiety for the supposed want of virility, or rather for the loss of health that is supposed to accrue from the too frequent involuntary excitement of the sexual centre and its natural physiological consequence. I do not know who coined the word spermatorrhœa, whether it was a quack or an honest man, but I do know that it figures as a disease on the nomenclature of the Royal College of Physicians, and that there are surgeons of repute, physicians also, perhaps, for aught I know, who still make use of the term, and who treat what they consider to be the disease. There is no such disease, and the occurrences that are supposed to indicate its existence are natural and physiological, the absence of which in some degree would be evidence of feebleness or of ill-health; and the more or less of which is the subject of much variation within the range of health. And I have this to say about seminal discharges, that they are troublesome or complained of in two classes of persons—the very muscularly strong, and in such as work hard and in consequence run into a state of nervous erethism. In either case a continent man is likely to suffer more in this way than is natural, but this is not to say that it is a disease that requires to be treated; it may be allowed to be a matter that admits of one visit to a doctor, but by him it is to be relegated to its proper position in the individual's mind by a short lecture upon the most elementary physiological principles.

Allied, again, to these cases of prostration comes another group, characterised only by emaciation. And here again one has need to be very careful not to overlook anything. But there can be no question that nervous exhaustion, or breakdown, or whatever we choose to call it, is capable of producing the most extreme wasting, quite apart from the existence of any disease. The most extreme instance of this that I have ever seen was in the case of a young man whom I had already known some ten years or more, and who was much given to worrying over trifles. Some sixteen years ago he walked into my room one day, and in doing so produced an electric sensation throughout me which I have never forgotten, for I could not get out of the idea that I had shaken hands with a corpse. He was an absolute skeleton, and his little wizen face had that peculiar appearance of the skin of the forehead that gives the idea that the skull is showing through it. Well, I examined him with the utmost care, and I could find no evidence of disease of any kind. I think that is good evidence that there was not much wrong, so far as gross disease was concerned, for in those early days I fancy that the errors we commit are not so much those of omission, but we often find diseases that have no real existence. Well, I could find nothing, but I did not nevertheless give up my opinion that had consigned him prematurely to the grave. I could not find anything, so much the worse for me; not the better for him. I still held to the idea that, concealed under the thin skirts of his fleshly covering, there lurked a something that was gnawing at his vitals. Indeed I believe I came the nearest I have ever done to believing in the popular notion, that perhaps he had a tapeworm. But in supposing that this man had some hidden disease that could not be discovered, I had overlooked the power of the disordered nervous system to produce the symptom that had alarmed me so much. I realised it afterwards to the full when week after week, sometimes day after day, he would come and talk by the half hour of his ailments, till sometimes I think my visage must have caught the reflection of the sickly light that shone so plain in his. However, his worries wore off, and his business, which was a harassing one, prospered, and his flesh came again to him, if not like the flesh of a little child, yet with sufficient plumpness for his needs, and that man is alive and well to-day. I could give you several others of like kind, if not quite so extreme in degree, but I have not time; but there can be no doubt about the influence of the nervous system in modifying nutrition in this way, and what is more, it is one of the most interesting subjects in the whole range of medicine and physiology. We talk about diet influencing the nutrition, and we diet fat people to make them thin, and thin people to make them fat. But I have never heard of this experiment being carried out yet: the taking twenty consecutive cases of obesity, treating them on the same plan, and publishing the results, and doing the fattening process on the lean kind in similar way. We hear of Mr. So-and-so's diet as a good thing because it has reduced one or perhaps two people, but I make bold to say that there is no diet that has ever been suggested that has not failed, and failed absolutely, in many more cases than it has ever succeeded in. There are some people, ay, many, whom you can never make thin, and there are many people, and those usually, and here is the point of its introduction here, of a nervous temperament whom, do what you will, you can never make fat. I see children, for instance, who are brought to me for an opinion because they are so thin; they are always eating, and yet never do any credit to their victuals, and they are fed up and made to take cod-liver oil, and maltine, and all the latter-day fatteners. But these children are always twitchy, half choreic, or excitable; and they belong, for the most part, to the nervous temperament. No good is done by stuffing them; on the contrary, their urine becomes loaded with solids, their intestine fails to digest properly, and they have repeated bilious attacks. Put them on an ordinary diet, perhaps rather a spare one, and plenty of water to drink, and though they do not get

Digitized by Google

fat they keep in much better health, and indeed they cease to give much anxiety to their parents.

And now that I am on the subject of children in this regard another condition comes to my mind that is very common: it is a neurotic condition, and one that is not fully apprehended in many cases. I allude to the pyrexia that is so often produced in young children by falls on the head, or blows of any kind in that region. It is quite common to be called to see a child who has been quite well till a certain day, when it has had an injury to its head by a fall or what not; and thereafter it has, within a day or two, become feverish, and in consequence the onset of meningitis is feared. I have seen cases of this kind repeatedly, and they have always seemed to be of considerable interest, because they may point to the injury of some heat centre or regulator. But I do not think this explanation is so probable as that the injury to the head leads to disordered nerve control over the viscera, which elaborate the blood and depurate it of effete matters, and that in consequence the pyrexia is a direct result of this faulty action of the viscera. And I believe head injuries of this kind are capable of inducing even definite disease in this way. For instance, some three years ago I saw a little boy of two years old who had been quite well. He had a fall on the 5th of the month. On the next day he was quite well, but on the 7th of the month he was very sleepy and wanted to stop in bed. He was seen by Mr. Stokes of Blackheath on the third day after his fall, and he then had a retracted neck, had vomited once, and he was still very drowsy. When I saw him his temperature was 101°, his pupils active, no intolerance, and I regarded it as one of the cases I am discussing. He remained in the same drowsy, irritable, indefinite state for a fortnight, and then slowly developed into a case of apical pneumonia that came on very slowly and obscurely, and which ultimately got quite well. Am I because of the result to alter my opinion of its cerebral origin and say the fall had nothing to do with the attack? Had I seen no other similar attacks I might be inclined to think so, but having seen many of somewhat similar character I stick to my guns, and I really believe that injuries to the head are quite capable, by interfering with the control power of the nervous centres, of leading to disordered function in the first instance, and in the second to such pronounced organic departures even as an acute pneumonia. I doubtless speak to those whose experience can supply other cases to which a like explanation would be not inappropriate. And here I must close for to-night with the remark that it often strikes me when dealing with such conditions as I have spoken of how intimate is their connexion with pronounced insanity. It is a happy thing that one can say for certain that such conditions as these go on for many years; but many of them pass out of notice, and we do not have the opportunity of seeing the result, and one cannot but think that in some of them, at any rate, one must see the beginnings of insanity; and in some of them, probably, the incipient stages of that most terrible of all its forms, the general paralysis of the insane.

THE BEARING OF RECENT BIOLOGICAL RESEARCHES ON THE PRACTICE OF MEDICINE AND SURGERY.

By G. SIMS WOODHEAD, M.D., F.R.C.P.EDIN.,
DIRECTOR OF THE LABORATORIES OF THE ROYAL COLLEGES OF PHYSICIANS (LOND.) AND SURGEONS (ENG.).

(*Continued from page 79.*)

WHERE there are no lesions of epithelial surfaces, and where the tissues are moderately healthy, bacteria cannot invade the body; or, if they do find their way in, they are killed off, comparatively rapidly. Accepting this statement, we are still confronted by the fact that patients, especially those treated in our large hospitals, are admitted because they are suffering from such lesions; in addition, from the very fact that they find it necessary to seek hospital shelter, they are often ill-clad, overworked, and badly nourished. Their hygienic surroundings are none of the best, and these acting on a weak constitution have further impaired any general vital powers ever possessed by them. (It must be remembered, however, that in this process a certain immunity by acclimatisation may have been acquired against some forms of disease, although the susceptibility to others may have been materially increased.) Such are the patients for whom antiseptic surgery was originally introduced. Their tissues were not able unaided to combat, the many micro-organismal agents found in our badly ventilated and often permanently infected wards before the system was introduced, and for such, in some form or other, it still remains necessary.

All will admit that patients in perfect health before an accident, if operated upon and kept under good hygienic conditions, supplied with good food and plenty of fresh air, will make a good recovery without excessive, or perhaps with a complete absence of, suppuration, and with no symptoms of pyæmia or even of septic absorption beyond a rise of temperature with other indications of a slight febrile condition. In a similar patient a large accumulation of serous fluid—in the chest, say, or of synovial fluid in the knee, or a mass of bruised and dead tissue—the result of a blow—may be slowly absorbed without the slightest trace of putrefaction or septic change being set up. Should, however, any dust from without or any dirty instruments be introduced into these masses of devitalised tissue, inflammation and more or less severe suppuration are at once set up, and an empyema, a purulent synovitis, or an abscess may be the result. In a weakened or anæmic patient with an open wound or with an accumulation of serum, an extravasation of blood or a mass of dead tissue, most of the conditions favouring septic mischief are present, and as he is placed in a ward with other patients, breathing the same air, dressed by the same hands, and operated on with the same instruments, the risks of septic mischief are enormously increased unless the strictest antiseptic precautions are taken (1) to remove any dead tissue on which the organisms might feed; (2) to prevent the access of micro-organisms to the wound or dead tissue—(*a*) from the cutaneous surface, or (*b*) from the lungs or alimentary canal; (3) to put the tissues under the best possible conditions, so that the phagocytes (or the blood serum, or both) may manifest their special protecting powers—in fact, to allow of what we call the healing power of nature to come into play; (4) to remove from the region of the patient, from dressings, and from instruments all organic and other matter which might possibly harbour putrefactive or septic germs. These I was taught by Lister (although he never spoke of phagocytes) to look upon as the main factors in the antiseptic system of treating surgical cases. Although the methods by which these ends are to be attained have necessarily been modified from time to time as experience has indicated fresh difficulties and suggested better means of obtaining the desired end, and although the kind of antiseptic used may have been altered (not always improved) as experiment and experience seem to have indicated certain advantages to be gained by the use of one or other reagent, the above principles as enunciated by Lister still remain unaltered, and I may be allowed to speak of some of these points.

Of the removal of dead tissue on which the organisms may feed it would at first sight seem unnecessary to speak; this has been so fully insisted on by even those who, "having no faith in antiseptics," all of whom acknowledge the necessity of carrying out this part of the system. The older surgeons, than whom none were more careful in observation, had a horror of all sloughs and dead matter in their wounds; and though many of them were delighted enough to see "healthy laudable pus" (healthy because it showed that the tissues were reacting, and were doing their work of localising the mischief as far as possible), they were glad enough to get rid of it. All accumulations, such as those above mentioned, necrosed bone and the like, once exposed to the air were removed as soon as possible, and even those that were not so exposed were frequently removed by incision or excision. It is now known that these, in weakened and unhealthy patients especially, were sources of danger, because decomposition changes were set up in them by the septic or other organisms which found their way to them, either directly from without through the broken cutaneous surfaces, or indirectly through diseased mucous membranes, and thence conveyed by fluids and cells deprived of their healthy or normal activity.

Let us take the case of puerperal fever, which is now recognised as resulting from the absorption of septic material from the cavity of the uterus. Under normal conditions

Digitized by Google

where the placenta is thoroughly detached, and there is no great hæmorrhage, the clots are soon removed, the discharge ceases, or appears to undergo no decomposition changes until the uterine wall has so far healed that a barrier to the absorption of the products of decomposition is built up, and no damage is done. If, on the other hand, fragments of placenta remain adherent and hæmorrhage occurs, the frequently broken surface continues to absorb for some time, and fever is the result. The introduction of scarlatinal, erysipelatous, or septic germs in either case is, as we know, attended with the most disastrous consequences, as even where the amount of hæmorrhage is comparatively small the blood that is present affords sufficient pabulum for the growth of the organisms, which once gaining a foothold have a coign of vantage from which to commence to form their poison, and in some cases from which to invade the tissues of their host. The practice of obstetricians was, *from* our present point of view, for long far in advance of that of surgeons in the matter of douches, cleanliness, and the like, but the general surgeon may certainly claim priority as regards the adoption of antiseptics on any systematic or methodical plan. The first cardinal rule with the obstetrician is that all matter that could possibly harbour germs or afford them sustenance of any kind is most scrupulously removed. The second and third rules, as stated by Lister, are attended to by constant application of antiseptic douches, especially where the wall of the uterus is more injured than usual, and the fourth rule is made much of as in general surgery.

This presence of dead material in wounds has always been looked upon as one of very great importance. Sloughs, masses of dead tissue, synovial fluid, serum, the fluids in the serous cavities, and even blood itself have been, and still are, considered, in the positions and under the conditions in which they are sometimes found, as being detrimental to the healing of wounds, and also as affording a nidus in which micro-organisms might flourish, however they might find their way into the wound or cavity. Lister, recognising the necessity of getting rid of this material, especially in the earlier days of his method, utilised indiarubber drainage-tubes, which in his hands and in the hands of those who followed out his method in all its details gave most admirable results. After a time, however, as the methods became simpler and more reliable, it became evident that there were many cases in which drainage-tubes were unnecessary, and which would be better treated by compression along with strict antiseptic dressing, especially where the parts could be left untouched for a considerable length of time; or by the use of a modified form of drain of chromatised antiseptic catgut, which could be left in position until absorbed, thus doing away with all necessity for disturbing the wound, the catgut being first absorbed in the deeper part, and disappearing entirely as the wound closed from below and just at those points where it was no longer needed. It has been objected that the presence of an indiarubber drainage-tube prevents the sides of the wound from coming together, and that many cases in which healing by first intention might be obtained are kept from so uniting and the recovery of the patient is somewhat retarded. The objections, however, do not end here. Any foreign body, as we have already seen, causes irritation and consequent exudation of both serum and leucocytes, and the tube by its presence keeps up a constant and sometimes prolonged discharge, as a result of which the dressings are saturated, they have to be removed more frequently, the wound is exposed, and the risk of infection is increased in proportion to the increased number of dressings required. Welch[1] points out that in addition to these objections there are two very important ones—viz., (1) That in these tubes any bacteria which may get in find protection against the "bactericidal influence of the tissues and animal juices"; and (2) that "bacteria may travel by continuous growth, or in other ways, down the sides of a drainage-tube, and so penetrate into a wound which they otherwise would not enter"; and he says, "we have repeatedly been able to demonstrate this mode of entrance into a wound of the white staphylococcus found so commonly in the epidermis." Anyone who has had to treat large suppurating wounds in which the granulation tissue has from time to time blocked the lateral holes in a drainage-tube knows how difficult it is to withdraw, clear, and shorten the tube without causing some hæmorrhage, and I remember well the regrets that were given utterance to by Lister and Chiene when they found it necessary to disturb the granulations by which the healing was being brought about, as they were thus compelled to undo part of the work that was already done; and, perhaps, even still more important, they had to disturb nature's barrier of active connective tissue cells well supplied with blood-vessels and leucocytes, set up to prevent the entrance of bacteria or their products from the wound. Drainage-tubes are no doubt necessary in certain cases; but Welch has well summed up as follows: "The advantage from the employment of drainage-tubes is, of course, the removal of secretions, and this indication becomes an urgent one if the cavity with which the tube communicates becomes infected and suppurates. In a given case the surgeon must weigh the advantages and disadvantages, and act according to his judgment. The practice of many surgeons at the present time of restricting within much narrower limits than formerly the use of drainage-tubes and of discarding them for all wounds which offer a fair prospect of primary union is a distinct advance in the technique of antiseptic surgery." Of the various methods of treating wounds without drainage it is now not necessary to speak; but one method of treatment cannot be passed over without something more than a mere reference. It has already been insisted that where there is any danger of micro-organisms finding their way to a blood-clot the very best treatment may be to evacuate the whole mass and then allow the wound to heal by granulation. Then, too, no one would think of leaving blood-clots in any serous cavity if he could possibly remove them without doing any injury to the peritoneum.

In the case of smaller cavities, however, and in healthy patients the removal of blood-clot is not necessary, and under antiseptic treatment the blood, even in considerable quantity, may be of very great value in serving to form a scaffolding (a scaffolding which is said to retain a certain amount of vitality) on which new tissue may be built up. The first two cases I saw of the actual application of what had been suggested by John Hunter were in the wards of Professor Lister and Mr. Chiene in the Edinburgh Royal Infirmary. The experiments were carried on independently, so far as I can remember, and within a very short time of one another. In Lister's case a long deep groove had for some reason or other been made in the front of the tibia. This groove or trough was allowed to fill with blood, after which the wound was dressed with the strictest antiseptic precautions. Each time as the wound was dressed and as the clot contracted fresh blood (obtained by simply pricking the clot) was run in until there had formed a mass of organised tissue which completely filled up the groove; periosteum grew over, and a capital result was obtained. Chiene's case[2] was of a somewhat similar nature. After the removal of a large horn from the heel of a patient a cavity of considerable size, forming a kind of box, with the os calcis as the floor, was left. This cavity, filled with blood and covered with "protective," was dressed antiseptically, and on the sixteenth day organisation had taken place in the clot, and the epithelium had commenced to grow in *from* the margins of the wound. There was, however, a hollow left; this was again filled with blood drawn from the now vascularised clot, and organisation took place. Unless antiseptic precautions are taken it would be impossible to obtain such organisation in blood-clot in an open wound; for although it is quite possible, nay, it has been actually proved, that freshly drawn blood has some power of inhibiting the growth of, or even of killing, certain micro-organisms, this power is soon lost, so that if exposed for any great length of time to the attacks of micro-organisms the clot must ultimately undergo decomposition changes, and so lose its value as a scaffolding into which connective tissue cells and young capillary vessels can make their way. Many surgeons have a dread of blood-clot in any position and under any circumstances, but now, owing to the above observations, and, according to Welch, especially as the result of the later observations of Schede (1886) and Halsted (last year), the filling in of wounds with blood-clot has to be recognised as an extremely useful method of obtaining healing. Lister insisted on the power of freshly drawn blood to resist the advance of putrefactive germs, and he indicated that these powers of resistance are much greater than we are usually inclined to allow. His observations have been confirmed and blood-clot has taken its place as a dressing.

On the other hand, no one will for a moment contend that blood-clot with its contained red blood-corpuscles is equal to the fibrinous lymph such as we obtain on an inflamed serous surface, for example, as a medium in which organisation may take place. It is a soft, plastic material, which, like lymph, may fill every space; by adhesion it keeps parts in apposition; it contains for a time active living cells, and then allows of their immigration, as bloodvessels come near it; and lastly, it is made up principally of a proteid substance which can be readily peptonised and removed as new cells and tissues come forward to take its place. Its great disadvantage, as compared with fibrinous lymph, is that it contains a large number of red blood-corpuscles and much soluble blood pigment, which appear to act as useless foreign bodies, and all of which must be absorbed before healing can take place, and in this process of absorption many active useful phagocytes are occupied when they might be engaged in the removal of effete necessary material. Here, again, it must be remembered that the less work the phagocyte has thrown on it to do the more rapid will be the process of healing. It is for this reason that so many surgeons allow bleeding to stop, then allow serous exudation to go on for some time, and then, and not till then, bring the two free surfaces together. Where spaces have to be filled in, a large enough quantity of coagulable lymph cannot be obtained, and the next best substitute, coagulated blood, is used in its place. This method may be used in any case where antiseptics are employed, and where the tissues of the patient give any help at all; but woe betide the operator who allows blood to get in where it should not be, so that tension is set up, or who allows bacteria to gain a footing on the surface of his clot. The only advice that can then be given is, "get rid of all the unorganised clot as soon as possible, and leave only that in which partial or complete organsation has taken place, or that part in which a protecting layer of granulation tissue has been formed." After saying all this, we may be compelled to come to the conclusion that "under good antiseptic technique[3] wounds will heal even when they are left entirely to themselves, whether drained, obliterated, or filled with blood." "Exudations composed of fluid and cells would greedily accumulate in most of the spaces, and the fluids and cell possess antibacterial properties as well as blood. Granulation tissue would spring up from the sides. I venture to predict that if the surgeon paid no particular attention to the filling or obliteration of many of the smaller spaces in fresh operation wounds, and if the antiseptic technique was good, the process of healing would be as satisfactory as by any of the other methods mentioned."[4]

The aim of Lister's second rule is to prevent the access of micro-organisms to the wound or dead tissue, for, as he pointed out, once there they can only be attacked by means of powerful chemical antiseptics, which necessarily exert a most injurious influence on the tissues which under ordinary circumstances require to retain all their vitality and activity in order that they may deal with the organisms which might under any circumstances find their way into the wound. Everyone knows how chloride of zinc in strong solution interferes with the absorption of septic poison from a septic surface after an operation in which the tissues have been damaged by bruising and cutting. It first acts as a powerful antiseptic, preventing the growth and development of the micro-organisms and the production of their poison in the tissues otherwise prepared for their reception; whilst after a time it also sets up great leucocyte exudation not only at the free surface amongst and beneath the dead tissues, but also beneath the surface, so that the lymph spaces are filled with both fluid and leucocytes, both of which, as we have seen, exert a certain bactericidal effect. We may say in fact that in such a case bacteria are kept in check by the antiseptic until the tissues have had time to throw up defences, a process in which they are assisted by the antiseptic itself, which acts as an irritant foreign body. Strong antiseptics may even be used to render wounds actually aseptic after the introduction of septic material from without. In a case of compound fracture where a large quantity of dirt has been pressed into the wound the thorough flushing out with strong carbolic acid solution has, in Lister's hands, as I have repeatedly seen, given the very best results. Here no doubt the result was effected partially, as above described, but another factor must not be left out of account. The strong irritant, acting on bruised and partially devitalised tissue, continued the devitalising process, rendered sloughing easier and accelerated the removal of all tissue that might interfere with the healing of the wound or that might afford a nidus for the growth of micro-organisms. In these cases special requirements are indicated, and each case has to be treated according to the ingenuity and judgment of the surgeon; and the man who has grasped the principles of treatment most firmly will invariably obtain the most satisfactory results.

It may be accepted that any antiseptic substance in a wound not naturally there is out of place.[5] The spray is not now so generally used as formerly, as its use is thought to be attended with no special advantage at all equal to the trouble that it involves. There can be no doubt, however, that at the time it was used it was a most important factor in the success of antiseptic surgery, and I for one am scarcely convinced even yet that the disfavour into which it has fallen is an unmixed blessing. It is stated that it created currents of air which brought dust into the region of the wound, and that the carbolic acid contained in it was not sufficient to kill organisms that came under its influence. Admitting all that, I cannot help thinking that it acted as a most efficient watering-cart, and that much of the surrounding dust was precipitated, and once down was held there by the carbolised water, and that for this reason, if for no other, its use added to the success of the earlier operations. I am of this opinion especially as I saw the series of experiments carried on by Professor Chiene and Mr. A. W. Hare, in which, out of a large number of vessels containing nutrient broth, some opened under the spray and some without it—all in the same room—the number of those in which growths occurred was far greater in those opened without the spray than in those opened with it. Greater care as to the washing of everything with an antiseptic lotion has in part taken its place, but, I am still inclined to believe, not entirely. Of dressings for the prevention of access of micro-organisms to a wound it has often been said that all that is necessary is to have an "aseptic" substance. Theoretically this is true enough, but practically it is very misleading, for as soon as a dressing becomes damped it becomes an excellent conducting path for the passage of micro-organisms, unless it contains some antiseptic substance which will interfere with the activity of, or actually destroy, the invading micro-organisms. It is an easy matter to keep a culture in a test-tube pure if free evaporation through the sterilised cotton wadding plug is allowed, even when dust is permitted to settle on its surface; but if the moisture is kept in by means of gummed paper, tinfoil, or indiarubber caps it is necessary to take the very greatest care to destroy all micro-organisms beneath the moisture-enclosing substance. Any antiseptic substance will act more or less as an irritant, and cases have been recorded in which the continuous washing out of a wound has kept up irritation and suppuration for a lengthened period. Where wounds are septic we have to choose the lesser of two evils, but where the wound is aseptic all that is necessary is to keep it so, and nature will do the rest. It will be necessary here to speak only of the micro-organisms that may come (1) directly from without, (2) from the skin, and (3) from the cavities and channels within the body.

(To be continued.)

[3] Welch, loc. cit.

[4] This opens up a much wider question, and one on the discussion of which we can scarcely enter at present, but for which we refer those specially interested to Professor Welch's paper.

[5] I well remember the pride with which I received Lister's commendation for reproducing this teaching of his, in a somewhat exaggerated form, in an examination paper sent in when I was a junior student of surgery; whilst later I was much impressed by a dictum of John Duncan's (a thorough believer in the utility of the antiseptic system), that if we thought more of the application of antiseptics to ourselves and less of the application to the wound, the patient would be the gainer.

ROYAL INSTITUTION.—Professor Victor Horsley, F.R.S., will on Tuesday next (January 19th) give the first of a course of twelve lectures on The Brain; Mr. A. S. Murray, LL.D., will on Thursday (Jan. 21st) give the first of a course of three lectures on some aspects of Greek Sculpture in Relief; and Professor J. A. Fleming will on Saturday (Jan. 23rd) give the first of a course of three lectures on the Induction Coil and Alternate Current Transformer. The Friday evening meetings will begin on January 22nd, when the Right Hon. Lord Rayleigh, F.R.S., will give a discourse on the Composition of Water.

PERINEAL DRAINAGE IN INVETERATE STRICTURE OF THE PENILE PART OF THE URETHRA.

BY C MANSELL MOULLIN, M.D.OXON., F.R.C.S.ENG.,
SURGEON TO THE LONDON HOSPITAL.

IT is a mistake to suppose that strictures of the penile part of the urethra are invariably, or even frequently, the result of cicatrisation. Occasionally the mucous lining is destroyed by injury for more or less of its circumference, or eaten through by ulceration; but nearly always, as Berkeley Hill and others have shown, if the urethra is laid open, the membrane can be dissected off, thinned and discoloured, it is true, but intact, and capable of being unfolded its whole width. The first beginning of a deep-seated stricture is usually either a granular patch on the surface or an inflammatory deposit in the substance of the mucous membrane—sometimes the one, sometimes the other; and it steadily increases little by little as fresh lymph is poured out around and beneath it, involving first the urethral and then the peri-urethral tissues, until at length it forms a definite obstruction. The problem in the treatment of stricture is how to ensure the absorption of this deposit without causing the addition of more.

Temporary relief may be obtained by division or dilatation; and occasionally, if the lymph is still soft and cellular, so that its absorption can be effected without loss of time, this leads to permanent cure. But such good fortune is exceptional; nearly always a hardened patch or an open ring is left in the substance of the wall, less elastic than the tissues near, and unable to yield smoothly and evenly when the folds of the mucous membrane are straightened out by the passage of the urine. There may not be sufficient obstruction to cause any difficulty, but there is enough to keep up irritation and make the stricture relapse. Each act of micturition strains and pulls upon the tender tissues around; fresh lymph is thrown out, and organisation begins and contraction is well established before the original induration has had time to disappear. Strictures relapse and recontract, not because they are formed of scar tissue (with a few exceptions), but because the remains of the old and hard inflammatory deposit act like the little thickened patches, or the papillary granulations that are left after gonorrhœa, and begin again the old vicious circle. What is wanted is something that will hasten the fatty degeneration of the old exudation and help the tissues to remove it before the irritation of its presence can lead to the formation of any more, or cause any fresh trouble.

Unhappily, the means at our disposal for hastening the disappearance of chronic inflammatory exudation from other parts of the body are useless, or worse than useless, when the urethra is involved. Counter irritation, for example, is impossible. Pressure cannot be employed. If a tight-fitting catheter is introduced and left, the stricture tissue softens, it is true, and appears to melt away in the same way and for the same reason that dense fasciæ and ligaments become softened when a joint is acutely inflamed; but the effect is quite as transient; and clinical experience has proved that strictures treated by rapid continuous dilatation alone are usually the first to relapse. The only method is to free the tissues from every source of irritation, and secure for them a long period of complete physiological rest. If this can be done the hardened lymph will slowly disappear, and the walls of the urethra become soft and yielding again. In other parts of the body the absorption of the products of chronic inflammation begins as soon as the irritation that gave rise to it ceases to act, and if only strictures can be placed under the same conditions the same result will follow; at least, in those of them in which there has been no destruction of the mucous membrane. The curability of stricture has been denied. I have already shown[1] that it is by no means uncommon after external urethrotomy, and I am prepared to go further, and assert that not only is this possible, but that, under certain circumstances, strictures of the penile part of the urethra (or at least some of them) are capable of undergoing a process of spontaneous absorption.

The occasional success that attends extreme dilatation after Otis's plan, and after free internal urethrotomy, is probably to be explained in this way: thorough stretching or division of the stricture places the part at rest for a sufficient length of time, and the inflammatory products in the wall undergo fatty degeneration and absorption before they can give rise to sufficient obstruction or irritation to lead to the production of any more; but the result is very uncertain, even in comparatively recent instances. In older ones, especially in those in which there is more than one stricture, there is only one plan by which sufficient rest can be ensured, and that is by opening the urethra behind, in the perineum, and allowing the whole of the urine to escape without coming near the affected part. It is true the measure is a severe one, giving rise to considerable inconvenience for some length of time, but it is not intended to make use of it unless the conditions are severe.

My attention was first drawn to this by noticing the way in which strictures of the urethra sometimes disappear spontaneously in cases of extravasation of urine. In August, 1887, a patient suffering from this complication in an extreme form was admitted into the London Hospital under my care. The history, so far as could be ascertained, was of the ordinary character—several attacks of gonorrhœa, increasing difficulty of micturition, complete retention, and then suddenly, a week before admission, rupture and extravasation. The patient's condition was deplorable: the putrid fluid had spread far above the umbilicus, back into the lumbar region, and even into the ischio-rectal fossæ, Colles' fascia having given way by sloughing. The pulse was very feeble, and it seemed doubtful if the patient could survive the night. However, an anæsthetic was given, the stricture examined, and found to be impassable, at any rate at the time. Free incisions were made wherever the fluid had penetrated, the first in the middle line of the perineum, with the view of opening up the membranous portion of the urethra and giving free exit to the contents of the bladder. Six weeks later, when the patient had rallied and the incisions were closing in, it was thought that the time had come to examine the condition of the urethra. The whole of the urine still passed through the perineal opening, and there was no sign that the obstruction had yielded in any way. However, on trying a small black bougie (No. 2, English) it slipped through almost at the first attempt, and by the end of a week, passing a catheter every day, all obstruction had disappeared and the walls of the urethra were as soft and flexible at the seat of the stricture as they were elsewhere.

I admit the altered behaviour of the stricture may be accounted for, to some extent, by the subsidence of spasm and congestion. Before the rupture occurred the mucous membrane must have been subjected to an extreme degree of pressure and irritation. After the operation, for six weeks it was absolutely at rest. But I do not think, in such a case as this, spasm and congestion are factors of much moment. The real change was in the dense gristly mass that surrounded the urethra and filled up all the interstices in and around the submucous tissue. Left absolutely quiet for six weeks, without anything to irritate it, it had gradually undergone a process of degeneration and been absorbed, so that when at length a bougie was passed the narrow part of the urethra could be unfolded and opened out at once. Whether the cure was permanent or not I am unhappily not in a position to prove; but it may be admitted on *a priori* grounds that even if the chance of this at any time is not very great, it is certainly greatest if the stricture tissue is thoroughly removed by fatty degeneration and absorption, not merely stretched and left.

Such a measure as this is, as I have already said, a severe one for ordinary cases, although, if the patient will spare the time and put up with the inconvenience, he will, I believe, be amply repaid in the future; but it is not uncommon to meet with instances in which a perineal incision is rendered advisable, and even necessary, by the presence of complications, and in which it can be made to assist in the absorption of the indurated mass. All that is required is that it should be kept open for a sufficient length of time. In one case, for example, that was under my care in 1890 there was a number of false passages spreading out in all directions, so that it was scarcely possible to find the orifice; and the urethra behind was so dilated that when it was incised a long cul-de-sac was found running in the corpus spongiosum, far beyond the stricture itself, almost into the glans. In another the median operation was performed for the purpose of extracting the broken end of a bougie. In a third the bladder was drained for severe cystitis and strangury; and in a fourth the whole length of the penile part of the urethra was affected more or less, and there was already the beginning of a peri-urethral abscess.

[1] THE LANCET, Sept. 19th, 1891.

Digitized by Google

In two of these internal urethrotomy was performed at the same time; in the others the stricture was simply left alone, and all the urine allowed to escape through the perineal wound. The length of time this was kept open varied from a month to six weeks, but I regard the longer period as usually necessary. In no case did any fistula persist—the difficulty is rather in the opposite direction. It is not easy without maintaining a drainage-tube, or occasionally employing dilatation, to prevent the opening contracting prematurely. In all the stricture tissue disappeared of itself, so far as could be ascertained with a bulbous sound. It was not stretched or dilated; it was merely left alone, and when a catheter was passed it apparently did nothing more than open out again the folds of the mucous membrane, which were still collapsed owing to the way in which they had been so long pressed together by the inflammatory exudation.

Wimpole street, W.

THE VERNACULAR MEDICINE AND SURGERY OF JAPAN.

BY BENJAMIN HOWARD, M.A., M.D., F.R.C.S.E.

IN aptitude, adaptation, and enterprise the Japanese have shown a decided superiority over all other nationalities of the Orient. These qualities added to great delicacy of manipulation have made them in art conspicuous throughout the world. It is but natural to expect, therefore, that they should be found to have arrived at something, both in medicine and surgery, which the nations of the West might find to be an acquisition. The earlier Japanese medicine dates back to the "Shindai," or divine age, many centuries before Christ. The Chinese, as early as 218 B.C., found their way amongst the Japanese doctors with medical books dating back, it is alleged, to 2737 B.C., and the influence of Chinese medicine upon Japanese medicine has continued to be a controlling one up to the recent introduction of European medicine now in vogue. As it is difficult to disentangle that past which is of Chinese origin, I include in the vernacular medicine and surgery of Japan all which pertained to its general practice, say, forty years ago, and which still pertains to the practice of about 30,000 out of the 41,000 physicians now practising throughout the Empire. Of the 30,000 of the old vernacular school one of them is still on the list of the Court physicians and maintains a high reputation.

The impression throughout Europe that coloured papers, exorcisms, &c, are the basis of Chinese and Japanese medicine is erroneous. I have myself seen nearly 2000 books by these people, covering most of the departments of medicine, but amongst which materia medica occupies altogether the leading place. In these books are the doctrines of the successive schools, strikingly like some of those which in past centuries existed amongst our own ancestors. The successive medical colleges have always had a professor of astrology, but the solid fact remains that the materia medica has included amongst its several hundred remedies a large number of those used by ourselves, and these are not only vegetable, but animal and mineral, in the latter class mercury being prominent. Surgery became a separate branch as long since as the seventh or eighth century. Tube acupuncture needles, so comparatively new with us, have been in use here since A.D. 1688. Centuries ago one of their authors wrote: "When medicines are ineffectual as well as acupuncture and the cautery, the abdomen and back may be opened, the stomach and intestines be washed, &c." A narcotic mixture employed on such occasions contained datura alba, aconitum, &c.

As the history of medicine in Japan once included so much which seems substantial I have inquired with much care amongst practitioners of the old or vernacular school—all of whom were in practice before 1876,—hoping to discover something in their practice now which would be a veritable addition to the medical resources of our European brethren. I am sorry to have to say that the result of my search has not met my anticipations. As far as I have been able to discover, the vernacular practice of Japan to-day, over the entire length and breadth of the empire which I have traversed, is entirely empirical. Rachitis being unknown, and the life led by the women being so much more natural than in Europe, obstetrics may scarcely be said to be needed, and certainly does not exist.

Syphilis, which came here from China in 1630, is treated in a manner which is the same in principle as the treatment I have seen practised in Nubia, where the patient for several hours at a time buries all the parts of his body except his head in the hot sands of the desert. In this excessively volcanic country the various hot springs which abound, and some of which are exceptionally hot, are the sovereign remedy. In these baths, some of which are fully exposed to public view, whole families, entirely nude, pass a large part of the time during their visit to the particular spa. In several cases I have not seen, but I have been told by the patients of results from them which certainly seem remarkably good. In acupuncture, which, as I have said, has been practised by the Japanese for many centuries, they exhibit very delicate manipulation. For six seng (3*d.*) one of the blind practitioners of this art will, without pain, insinuate a long needle into your stomach, intestines, arms, legs—almost any part except the eye and the brain. The conditions for which it is held in particularly high esteem are flatuence and colic; next, perhaps, in order for neuralgia and rheumatism of the joints. From my own experience I can say it is almost absolutely painless. The points to be penetrated are not entirely arbitrary, but are determined by astrological indications. It is a noticeable experience to see one of these poor blind men take from the folds of his "kimono," or robe, a case of beautifully bright long needles of gold, steel, or silver, and with the *nonchalance* of the Oriental, and without the slightest pause in his conversation, to see him burying his needles two, four, or six inches in various parts of your person in a way which would astonish a European professor of surgery. I mention this practice only as a pretty display of manual dexterity, not as a practice to be imitated. There is one medical procedure, however, in which the Japanese can teach us something in every particular. I refer to their manner of practising massage. For reasons sufficiently apparent, the number of blind in Japan, as in all Eastern countries, is enormous. Every blind boy or girl is expected to join the one guild which is exclusively their own and be an "ammah." With their small hands and supple limbs they give to massage a variety and a delicacy not approached even in India. To what extent anatomy enters into their training I do not know, but no duly qualified surgeon could seem to be more intimately acquainted with the formation of the joints and the course of the nerves as a guide to manipulation. As to percussion, they obtain it by a semi-rotation of the hand with a velocity so great as to make the movement almost invisible. The deeper structures external to the joints they get at with the olecranon process of the naked elbow, which, by an equally rapid movement of the forearm, reaches every interstice with a force regulated with the greatest delicacy. For the muscles of the back, as in lumbago, the "ammah" frequently use their feet, with which they are almost as dexterous as with their hands. When great force is desired this is very efficient. Plain rubbing, which is the principal part of massage in Europe, would be beneath their dignity. Nearly every one of their various manipulations includes some delicate manœuvre which excites one's surprise and admiration. So common is massage in Japan that on arriving at an hotel—next to the tea, which is always immediately brought—the "ammah" is the individual who will surely appear. For the superficial or general massage at such time the tariff price is six seng (or 3*d.*); but a European is expected to pay two or three times as much as that, unless he can talk Japanese, in which case he generally does not. I have had massage in Sweden, which I thought perfection; I have had it in Turkey, which I thought otherwise; I have had it in India, and found it in most instances too rough and indiscriminate; but with a good "ammah" or masseur in Japan I have had but one regret, which is that my friends at home could not share my advantage.

Another lesson we might learn from the Japanese with probable advantage is the more general use of the moxa. For almost any pain whatsoever, if persistent and if at all deep-seated, the remedy throughout the country is the moxa. Whereas with ourselves the moxa is, even with a surgeon, a very unusual remedy, its use here is one of the female accomplishments in almost every household. A cone of cotton-wool previously saturated with a decoction of the Artemesia vulgaris latifolia is placed upon the part concerned, and being lighted is allowed to slowly smoulder to ashes. It leaves a superficial eschar, which seems to heal without special attention. The performance is often seen going on in passing a house, a woman operating on a man, woman, or child, and dressing the patient's hair, perhaps, at the same time. I have therefore inferred

Digitized by Google

the procedure is much less painful than might be supposed. The sore is clean, exactly the size wished, and must often be a very useful counter-irritant. In the public baths I have counted on men, women, and children, as many as thirty or forty discoloured spots from this cause, a row being commonly seen on either side the spine, and many other marks on the limbs, especially in the vicinity of the joints. To get the same amount of counter-irritation, we should certainly disable the patient from any active occupation and compel a good deal of inconvenient dressing, all of which, if the counter-irritation was to be maintained, would require repetition. In hygienic matters the Japanese have everywhere a habit which also may have a lesson for us. In their nightly bath and morning wash the water is never cold, never warm, but always as hot as it can be borne. To foreigners this habit seems very surprising, but the most inveterate Englishman, if he stays in the country long enough, abandons his cold tub in its favour. The cold-taking which it is suspected must follow it is found not to occur if the water has been hot enough. This heat is maintained by a little furnace beneath the bath. In the bath the bather or bathers take a prolonged soaking, the washing proper being done on the bath-room floor; then follows a second and final soaking, drying with towel, and a lounge in bathing wrapper. This habit seems to promote softness and suppleness of the skin, and by persons inclined to rheumatism is soon found to be altogether preferable to the cold bath in every particular. The poorest of the Japanese hear of a cold bath with amazement, and would be sure the man who used it must be a barbarian. With respect to the superiority of the hot bath over the cold, I have come to find that in my own case certainly the Japanese are right.

The Paper Ice-bag.—From a pocket-handkerchief to an umbrella it is difficult to say what is not made out of paper, and everything made out of paper is comparatively cheap. The ice-bag is a very favourite remedy, both in private and in hospital practice. The ice is generally applied in bags suspended so that the patient may get the cold from it without its weight coming upon the affected part. These pretty little bags are always made of thin paper. They are much cheaper than the oil silk used by ourselves that, whether they become broken or not, they can be frequently renewed, and this, in a large hospital with surgical cases, is an important consideration. The texture is softer, it adapts itself better to the parts to which it is applied, and in a private patient one of these paper ice-bags will easily last in constant use for several days. They would be a valuable acquisition in English hospitals. I enclose one of them, that the Editors of THE LANCET may form their own opinion of it.

It will be observed that the only things I have thought worth recommending are rather outside than inside the lines of strict medicine and surgery. It would seem that the decline in medicine must have been as great as the decline in the prevailing religions; hence the alacrity with which the foreign systems of both were seized by this hungry people as soon as presented. The Japanese massage, then, the Japanese bath, and the Japanese paper ice-bag are things which might certainly be regarded in Europe as useful acquisitions.

ON THE ORIGIN AND SPREAD OF LEPROSY AT PARCENT IN SPAIN.

BY GEORGE THIN, M.D.

ONE of the chapters in the book on Leprosy which I have recently published discusses the evidence in favour of the contagiousness of the disease, and refers to a number of facts which I believe to be of great assistance in coming to a decision regarding that very important question. As part of this evidence a brief account is given of the origin and spread of an epidemic of leprosy at Parcent, in the province of Alicante, in Spain. The facts, as stated in my book, are abstracted from the *Annales de Derm. et de Syph.*, vol. ix., p. 390, the information there given constituting part of a memoir presented by Dr. Zuriaga to the Municipal Council of Valencia, and translated into French by Dr. Paul Raymond. As these statements are available to those who are interested in the matter, it is not necessary for me to recapitulate them here in detail. Considering, however, the very important bearing of the evidence and the significance of the whole question, I thought it advisable to obtain independent and confirmatory evidence regarding this outbreak. Dr. Zuriaga relates how a leper from the neighbouring town of Sagra came to reside in Parcent in 1850, where, at the time, there were no cases of leprosy. He there lived on the most intimate terms with a certain Vincent Poquet Andrés, the two friends eating from the same plates, with the same spoon, drinking from the same glass, and sleeping together. Within a year Poquet had acquired leprosy from his friend. From Poquet the disease spread, until up to the date of the memoir there had been about sixty cases of leprosy in the small village of Parcent, of whom forty-five had died.

In a considerable number of those lepers who were affected at an early stage of the epidemic the precise source of contagion was ascertained, and is described in Dr. Zuriaga's paper. Certain individuals were infected by Poquet, and members of their families and their friends, who were living in close association with them, were affected first, until, finally, a sufficient number of persons had become lepers to make it difficult to trace, in new cases, the exact sources of the original infection. By the kindness of my friend, Dr. Garcia Lopez of the mines of Rio Tinto, I have been able to obtain a copy of a report on Leprosy in the province of Alicante, Spain, by Dr. Oswaldo Codina, dated July, 1887, and presented to the Director-General of Public Health in Madrid, by whom he had been commissioned to inquire into the nature of the epidemic. I was unfortunately unable to obtain a copy of this report until after the publication of my book; but its contents are sufficiently important to justify me in now bringing the facts on which it is based before the profession. Dr. Codina, like Dr. Zuriaga, has satisfied himself that leprosy began in Parcent in 1850 by Vincent Poquet Andrés acquiring the disease from a leper from Sagra, who had arrived from the Philippine Islands, and who was known by the nickname of "El Indiano," and with whom Poquet lived on intimate terms. The friends, who were closely associated with these two affected persons, were after them the first to become leprous in Parcent. This entirely verifies the account given in my book. Dr. Codina confirms Dr. Zuriaga's statement that a nephew, who frequented his uncle's house, became leprous; and contributes the additional information that a cousin of Vincent's contracted the disease in 1857. Amongst the instances of contagion given in Dr. Zuriaga's report is that of one Joseph Mora, who was on terms of intimate friendship with Vincent Poquet, a fact that is confirmed by Dr. Codina. Dr. Codina does not relate in detail the further cases which I have abstracted in the book, but he remarks that there is a chain of evidence which links the subsequent cases together, the disease developing itself in those who associated with friends who were already leprous.

Dr. Codina relates how the disease, having once established itself in Parcent, spread to the nearest towns, and shows in the table which he appends to his report how Parcent has been the principal focus of the disease in that neighbourhood. Poquet had numerous connexions, which accounts, Dr. Codina believes, for the considerable number of cases of leprosy which occurred in the family. Those who shunned them, he relates, remained free from the disease. He further relates how, when leprosy spread from Parcent to the neighbouring towns, the first to become leprous was always someone who frequently visited Parcent, such as Frances Sirera in Murla, and Nicolas Poquet in Laguart. A mother gave her son to a wet-nurse who was leprous, and the infant soon showed symptoms of the disease, and at the date of the report was in the last stage of the malady. A brother of this child became leprous and committed suicide in the year previous to the date of the report (1886), being unwilling any longer to endure his sufferings. No case of the disease had occurred previously in this family. Dr. Codina relates that in Pedreguer the development of leprosy has to a considerable extent been arrested on account of an imperfect isolation of the affected persons in country houses. He describes how the isolation is incomplete, as the lepers are allowed to be visited by their children, wives, and friends. The disease was originally imported into Pedreguer in 1809 by the son of a schoolmistress of Denia who came there, and who was a leper; and since that time leprosy has always existed in the town, although from the beginning some steps were taken to attempt to isolate the cases. In other towns of this district which he has visited lepers and persons in good health mingled at church and market, and had their clothes washed in the same places. There is nothing to note clinically regarding the cases of leprosy referred to by Dr. Codina, who describes as an example a severe case in a woman, in whom the distinctive symptoms of developed leprosy were

Digitized by Google

present. All the cases, he remarks, are not so pronounced as the one described as an example. He particularly alludes to the common symptoms of loss of the eyebrows, the peculiar dull expression of face, spots on the face, cutaneous tubercles, sometimes prominent, sometimes only to be felt by the finger, shining, parchment-like skin, cracked hands, scabby nails, with ulceration more or less extensive, and occasionally very severe. The invasion of the mucous membranes and special implication of the nerves and eyes are noted.

I do not consider it necessary to take up more space by a full translation of Dr. Codina's account of the symptoms observed by him in the patients at Alicante. The lepers in that district show, he remarks, a tendency to isolate themselves in the country and shun observation, and for this reason it is difficult to ascertain their exact number, more particularly as they do not seek medical assistance. They remain unseen as long as they can, only going out at such hours as will expose them least to observation. Although from the tendency to hide cases of leprosy and other causes it has been found very difficult to trace the history of the disease in this part of Spain, Dr. Codina is of opinion that there has been in recent years a recrudescence of the malady.

The disposition of the disease to adhere to certain families is well known. The following history of leprosy in a particular family, which has been worked out by Dr. Codina, may be given as a fair example of this tendency:—

GENEALOGICAL TREE OF THE FAMILY OF LLORET OF PEGO.

1.
Felipe Lloret, born 17—, died 1830; not leprous.
Vicenta Castaños (his wife); leprous.

2.
Enrique Lloret, born 1814, died 1874; leprous.
His wife (not leprous) died unattacked.

3.

Enrique, born 1832; lives not leprous. His wife (not leprous) lives unattacked.	Pedro (died leprous).	José (died leprous).	Maria (lives leprous).	Vicente (lives not leprous).

4.

Enrique, born 1859; lives not leprous. Encarnacion Sastre (his wife); no leprosy in family lives unattacked.	Encarnacion Lloret, born 1853; leprous for six years. Vicente Ciscar (no leprosy in family); her husband leprous for three years.

5.

Their son, born 1885, lives unattacked.	Maria, born 1887 (not leprous).	Encarnacion, born 1875 (became leprous in 1886).	Enrique, born 1883 (not leprous).

Here is a family in which we know that leprosy has occurred amongst some of its members for five generations. It is interesting to observe that in the third generation a son, who still lives unattacked by the disease, and who has married a wife equally free from it, has a daughter who at the date of the report had been leprous for six years, her husband, in whose family there was no previous case of leprosy, having been then leprous for three years. The history of such a family explains how readily the idea of the disease being hereditary has been adopted. It is only in recent years that a sufficient analysis of facts has shown the fallacies that have led to the acceptance of the idea that leprosy is hereditary, the history of the Norwegian lepers who emigrated to America having, I believe, very clearly shown that the disease propagates itself in certain families on account of the intimate contact which the members have with each other, and that when the conditions of life are such that this intimate contact is avoided the leprosy dies out. It is to Hansen that we chiefly owe the establishment of this fact, and the statistics on which it is based are set forth in my book. I believe that if this family of Lloret had lived under similar conditions to those prevailing amongst well-to-do people in the United States there would have been no leprosy now in this fifth generation, and am convinced that it is only by a general acceptance of this fact, and by the introduction amongst leper families of the habits which are its necessary corollary, that the disease will be exterminated.

Dr. Codina terminates his report to the Director-General of Public Health by submitting to him the following conclusions: "1. Leprosy has existed in the province of Alicante at least since last century. 2. The disease appears to have spread since 1809, and from Parcent especially, since 1850, it has spread to the neighbouring towns in an alarming manner. 3. Leprosy is not at present limited to a small number of towns. Not only are the towns belonging to the district of Parcent infected, but many others in the province; and, spreading over its boundary, the disease has affected some towns in the province of Valencia, where it has made considerable progress. 4. When leprosy has once appeared in a town it remains there, and cases are followed by others in an increasing proportion. 5. Leprosy is transmitted by inheritance, and, although many authors deny its contagious nature, the numerous cases which exist in the sea-coast towns, and its march and manner of propagation, incline us to admit that this cause has been the most powerful one in bringing leprosy to the present state of development. 6. The necessity of building a hospital for lepers should be insisted upon as the only means to prevent the further development of the disease. 7. Whilst lepers are not isolated, it is necessary to prevent all association with them, and oblige them to go out wearing shoes and gloves. All articles for their use or wearing should not be used by anybody else. 8. Inheritance being one of the causes of development of leprosy, lepers should not be allowed to marry. 9. They should be well attended to, and good food procured for them. Care must be taken not to allow them to come into contact, in business or otherwise, with healthy persons. 10. The authorities should give particular attention to the improvement of the sanitary conditions of towns."

The following table, copied literally from Dr. Codina's report, deserves careful study:—

"*Table showing the Cases of Leprosy in the Towns referred to in this Report.*

Towns.	No. of Inhabitants.	Date of Invasion.	Cases up to 1887.	Lepers existing. Males.	Females.	Total.	Remarks.
Parcent ..	150	1850	65	21	7	28	I gathered the data stated in the present table during my visit to the towns in the district of Parcent. Although I have endeavoured to obtain by information as accurately as possible, I am unable to guarantee its correctness. The towns sometimes hide the truth as to the number of lepers existing, and I may perhaps have made some mistakes; but if there are any, they will consist in showing too small, rather than too great, a number of lepers."
Laguart ..	400	1868	31	20	5	25	
Pego	1200	17—	—	14	6	20	
Orba	160	1873	25	12	6	18	
Pedreguer ..	720	1809	79	9	3	12	
Murla	120	1870	14	8	2	10	
Sagra	100	1848	13	5	3	8	
Benidoleig ..	80	1869	7	4	1	5	
Gata	440	1860	8	3	1	4	
Jalon	560	1867	8	2	1	3	
Denia	650	17—	—	3	1	4	
Oudara ..	325	1862	7	2	1	3	
Tounos	80	1860	10	2	1	3

The towns enumerated in the above table are contained within an area of twenty-four square miles, some of them being situated close together, and some (such as Pego, Laguart, and Alcahali) being isolated to the extent of a two hours' walk.

An examination of this table shows that the proportion of lepers in the towns bears no proportion to the number of the inhabitants. I am assured by the Spanish gentleman to whom I am indebted for a translation of the passages of the report that they are all situated near each other, and that the same hygienic conditions apply to them all. There is nothing in the soil, occupation, food, or race to account for any difference in the number of lepers which are to be found in these towns respectively. It also shows that the proportion of lepers to the population of the towns is not connected with the length of time that the disease has lasted, and therefore is not in relation to the opportunities given by heredity, even if it were assumed that heredity was a cause. Parcent, which is the most striking example, shows in twenty-seven years, in a population of 150 inhabitants, 65 cases of leprosy, of whom 28 were living at the end of that period; whilst Pego, with 1200 inhabitants, and where the disease has lasted since last century, had only 20 living lepers. Pedreguer, in which we know there was leprosy in 1809, with a population of 720, had in about forty years 79 lepers, of whom 12 were living at the date of the report; whilst Murla, with only 120 inhabitants, had had 14 cases in seventeen years, of whom 10 were living at the date of the report.

Excluding heredity as an insufficient cause of these cases, and as otherwise being discredited, the difference of the rate of increase of leprosy in these similarly situated villages is best explained by the assumption that the opportunities for contagion have been greater in some cases than in others, even if we did not have the statements which I have collected from two independent sources—namely, from the Mayor of Parcent, referred to by Dr. Zuriaga, and from Dr. Codina's report to the Director-General at Madrid. Another sad fact comes out from a study of this table—namely, that in many of the towns the appearance of the disease is comparatively recent and that in this part of Spain leprosy is spreading. The necessity for a hospital in Parcent seems to have been realised at last, for we find that a commission visited the neighbourhood in June, 1887, for the purpose of finding a site, and were offered one by the municipal corporation free of cost.

The above abstract is sufficient to show that Dr. Codina has entirely confirmed what has been written by Dr. Zuriaga, although in his report the history of contagion from one person to another is not continued in the same detail. I therefore recommend those who doubt that leprosy is contagious—and it appears there are many such doubters—to read Dr. Raymond's translation of Dr. Zuriaga's original paper or the summary of it which I have given in my book.

Queen Anne-street, W.

THE

TREATMENT OF "ATTIC" SUPPURATION BY EXCISION OF THE MEMBRANA TYMPANI AND AUDITORY OSSICLES.[1]

BY WILLIAM MILLIGAN, M.B., C.M.,

ASSISTANT SURGEON TO THE MANCHESTER INSTITUTION FOR DISEASES OF THE EAR, ASSISTANT PHYSICIAN TO THE MANCHESTER HOSPITAL FOR DISEASES OF THE THROAT.

THE region of the middle ear, known as the tympanic attic, is the space lying above the level of the short process of the malleus. The boundaries are, externally, the flaccid membrane and the outer osseous wall of the drum cavity; internally, the malleus, neck and head, and the anvil; above the superior ligament of the malleus; and below the short process of the malleus. This region is divided by numerous folds of mucous membrane into spaces of varying size, which, although of comparatively small importance anatomically, are most important from a pathological point of view. On account of the want of free communication between these several spaces, great difficulty is encountered in thoroughly cleansing this region when diseased. The spaces are partly closed, partly communicate with one another, and with the remaining portion of the tympanic cavity. Retention of secretion is favoured by the mechanical arrangement of the parts, with the result that caries of the head of the malleus and of the incus or of the surrounding bony parietes is common. Suppuration here is also frequently associated with other lesions—for example, with extensive perforations in other parts of the membrana tympani, with luxations of the ossicular joints, and with disease of the mastoid antrum. The frequency with which suppurative inflammation is found in the tympanic attic is variously stated by different authors. Randall, in an analysis of 500 cases, found attic suppuration present fifteen times; in another analysis of 2000 cases he found it present fifty times. In 375 cases which I have analysed I have found it present twelve times, or in 3½ per cent. of the cases. There is no doubt that it is one of the rarer forms of middle ear disease; but I am inclined to think that its frequency has been underestimated rather than the reverse. Although not of common origin, its importance demands careful consideration.

As regards the etiology of this condition, it has for long been a vexed question as to how suppurative inflammation localises itself in the cells lying behind Shrapnell's membrane. Walb[2] holds that the inflammatory process is propagated along the external auditory meatus. He believes either that an otitis externa circumscripta has affected the point between the membrana flaccida and the wall of the external meatus, or that an otitis externa diffusa has encroached upon Shrapnell's membrane, or that a disease of the external ear accompanied by secretion has produced an infection of the tympanic cavity inside the membrana flaccida through the foramen Rivini. He believes in the existence of this foramen. Most authors, however, hold that the affection is of "tubal" origin, and secondary to pharyngeal or naso-pharyngeal disease. Primary acute inflammation involving Shrapnell's cells is rare. The majority of cases run a chronic course, and, either from the frequent occurrence of a second perforation in a different part of the membrana tympani or from their clinical history, suggest the tubal origin of the disease. Thus it is not uncommon to find an open perforation in Shrapnell's membrane and a cicatrised perforation in some other portion of the drumhead, indicating probably that originally the whole middle ear had been involved, but that, whereas the suppuration had either been cured or had spontaneously ceased in the lower portion of the middle ear, it had remained persistent in the spaces lying behind the membrana flaccida. The fact that we have in this part of the ear a series of spaces not readily communicating with one another, and easily shut off from the general tympanic cavity by inflammatory adhesions, seems to me sufficient to explain how suppuration, if once established here, should tend to become chronic. Kretschmann[3] holds that the tympanic cavity is first involved, and following this the ossicles are attacked with caries owing to retention and decomposition of secretion. The analysis of clinical records also goes far to show that attic suppuration is a secondary affection. Schmiegelow,[4] in 37 cases, could find no immediate cause in 9; in 5 the affection came on during an acute inflammation of the nose and naso-pharynx, and in 4 it began apparently as an acute middle-ear catarrh; 12 patients referred the disease to childhood, but were unable to assign any definite cause; in 2 cases the affection followed scarlet fever, and in 2 cases a box upon the ear. In 12 cases which have recently come under my care, the disease was secondary to scarlet fever in 6, and to naso pharyngeal catarrh in 2. In the other 4 cases no definite cause could be assigned. To accept Walb's theory we are almost bound to admit the presence of the foramen Rivini, a foramen whose existence is denied by most anatomists. In those cases where the disease has lasted a long time, and its course is usually very chronic, the ossicles, although apparently healthy, will frequently be found diseased. Careful exploration with a fine probe will reveal carious spots unnoticed during inspection. The surrounding bony parietes are also often affected. Inflammation of the tympanic mucous membrane leads rapidly to caries as the mucous coat serves also as the periosteal lining. The intimate relations existing between the temporal diploic veins and the cerebral sinuses make bone disease here a serious complication. Of the three ossicles the incus is the one most frequently found diseased.

Ludwig,[5] in 32 cases of hammer-anvil extraction, found the incus carious in 11, or 34 per cent., both malleus and incus in 16, or 50 per cent.; the incus was thus carious in 27, or 84 per cent. of the cases. The stapes is seldom affected.[6] When it is, the disease is usually confined to its arms. The foot-plate having a more intimate blood-supply escapes. The incus unfortunately is frequently not to be detected by the eye or the probe, and hence disease here is not to be diagnosed with certainty. Yet according to some authors disease of this ossicle is frequently the cause of keeping up suppuration. Some surgeons accordingly advise that the two ossicles—the malleus and the incus—should always be removed together.

The treatment of "attic" suppuration is at all times tedious. In fact, no cases of ear disease tax the resources of the surgeon and the patience of the patient so much as do these cases. The importance of thorough eradication of the disease is, however, at once evident when we recollect the relation of this space to the base of the brain, the mastoid antrum, and the lateral sinus. The ordinary methods of treatment by the use of lotions, caustic applications, and the insufflation of various powders will generally be found insufficient, as the source of the disease is seldom reached by any of these means. Thorough irrigation of the attic by means of Hartmann's cannula or Blake's syringe may at times be successful, but the method is tedious and uncertain. Solutions of corrosive sublimate (1 in 2000), resorcin (2-3 per cent.), or peroxide of hydrogen may be used for this purpose. Schubert,[7] however, finds that irrigations into the tympanic attic are in general unsatisfactory. The question of excising one or more of the diseased ossicles and the remaining portions of the membrana tympani was first proposed by Schwartze, and has since been frequently accomplished. The indications for the operation are: (1) chronic purulency of the middle ear, with caries of the ossicles, and (2) the presence of cholesteatomata in the drum cavity. In those cases where carious spots are found in the walls of the middle or external ear careful scraping must at the same time be resorted to. The main points to keep in view are: (1) the thorough removal of all foci of disease, and (2) the establishment of free drainage. The results of the operation are gratifying. Ludwig,[8] in 32 cases operated upon, found suppuration ceased in 20 cases, with regeneration of the membrana tympani five times, without regeneration of the membrane fifteen times. Eleven cases at the time of writing were still under treatment; 1 case had died, but not in consequence of the operation. Burnett[9] records a case of chronic purulency of six years' standing which had resisted all the ordinary methods of treatment. He excised the malleus and the membrana tympani, with the result that the purulent discharge ceased and the hearing power improved. Sexton[10] strongly advises this operation. He records 29 cases where this method of procedure was adopted. Colles[11] relates 13 cases with 8 cures, and 5 in which there was great improvement in hearing, in freedom from earache, tinnitus, and vertigo. Wetzel, Rheinhardt, Kessel, and others also endorse the value of this operation. I have lately had the opportunity of performing this operation four times, in each case with complete cure of the purulency, and in all with subsequent improvement in the hearing power. To perform the operation a strong light is essential. Some surgeons prefer the electric photophore of Trouvé, worn upon the forehead; others prefer Sexton's electric lamp. The ordinary forehead-mirror reflecting the light from a good lime-light apparatus answers every possible requirement. A general anæsthetic is essential. Previous to the operation, the ear should be carefully irrigated with warm carbolic or boracic lotion several times daily. The auricle should be cleaned with turpentine or ether, and kept covered with a carbolised towel. In order to minimise hæmorrhage from the incisions, a 20 per cent. solution of cocaine kept in the external meatus for five minutes previous to operating will be found useful. If the membrana vibrans be intact, which it very rarely is in these cases, a circular incision should be made $\frac{1}{10}$th of an inch from its attachment to the tympanic ring. The tendon of the tensor tympanic muscle is then to be cut close to its insertion into the long process of the malleus. The superior ligament of the malleus is then divided. A curved knife must now be passed, and the ligaments connecting the malleo-incudal joint severed. The malleus will now be free, and may be removed by means of forceps or by the snare. If the incus is also to be removed, it must be drawn down by a fine hook—e.g., that of Kretschmann, Ludwig, or Ferrer,—and the ligaments uniting it to the stapes severed. The ear should then be irrigated with warm boracic lotion and carefully dried. Finely pulverised iodoform should be insufflated into the ear, and the meatus lightly packed with iodoform wool. Slight oozing is apt to follow the operation for the first few days. If the dressings become moist they must be changed. The drier the parts are kept the quicker is the process of repair. In each of the following four cases the malleus alone was removed.

CASE 1.—E. B——, female aged twenty-four, suffered from an attack of scarlet fever eight years ago. During the fever the right middle ear was attacked by suppurative inflammation, and has since then continued discharging. At times the discharge was very fetid, and at times streaked with blood. The patient has been subject to frequent attacks of vertigo, tinnitus, and pain in the ear. The hearing power had gradually become worse and worse. On presenting herself for examination it was found to be $\frac{6}{20}$ of the normal, as tested by the watch. A large, soft, gelatinous polypus was found growing from the upper portion of the tympanic cavity, and protruding through a perforation in Schrapnell's membrane. On being removed the malleus was carefully examined with the probe, and found carious. Injections into the tympanic attic with Hartmann's cannula were first of all made, but without in any way influencing the course of the disease. It was accordingly decided to remove the diseased ossicle and the remaining portion of the membrana tympani. The operation was carried out as previously described. Slight discharge of pus was found in the meatus twelve hours after the operation. The dressings were accordingly changed, and the ear packed lightly with iodoform powder. Since then the ear has remained dry. Ten months after the operation the following condition was found. Springing from the fringe of membrane originally left was a new membrane of a dull, opaque, lustreless appearance. The attacks of pain and vertigo had entirely subsided, and the hearing power, which previous to the operation had been $\frac{6}{20}$ of the normal, was $\frac{15}{20}$. For conversation the hearing had also decidely improved.

CASE 2.—M. W——, female aged thirty-four, had suffered since childhood from purulent middle-ear disease on the left side. Recurrent attacks of pain were frequent, and the discharge was at times very fetid. The hearing power had been considerably damaged, measuring only $\frac{5}{20}$ of the normal. On examination a large, soft polypus was found protruding through the upper part of the membrana tympani. The superior and posterior walls of the tympanic attic and the posterior wall of the external meatus were found carious. The head of the malleus was embedded in soft granulations. It was decided (1) to remove the polypus, (2) to remove the diseased ossicle, and (3) to scrape the diseased bony parietes. The operation was conducted as in the previous case. The process of repair went on uninterruptedly, and now, seven months after the operation, a new membrane has formed and the hearing power has improved wonderfully, measuring $\frac{18}{20}$ of the normal, or practically perfect hearing power.

CASE 3.—M. M——, female aged twenty-six, had suffered from purulent disease of the right middle ear for twenty-one months. There had been previous disease of this ear during childhood, and the patient was unable to state definitely if the discharge had ever really ceased. On the left membrana tympani a cicatrised perforation was found. Constant tinnitus and occasional severe pain were felt upon the right side of the head. On examination the right membrane was found almost completely destroyed. The long process of the malleus was seen hanging free in the meatus, and the short process was embedded in granulations. Local applications of various kinds having failed to arrest the suppuration, the malleus was excised, and the tympanic attic thus freely opened up. Three days after the operation the dressings were changed. Since that time, now eight months ago, there has been no suppuration; the pain and the tinnitus have ceased, and the hearing power has improved. Previous to operation it was $\frac{2}{20}$ of the normal. At the last examination it had improved to $\frac{12}{20}$, or a gain of 18 in. A new membrane is in process of formation.

CASE 4.—E. M——, female aged six, had a severe attack of typhoid fever fifteen months ago. During the fever both

middle ears were attacked by suppurative inflammation, and since then have discharged freely, especially the right ear. Pain has been occasional, especially on the child's taking any fresh cold. On examination both membranes were found extensively destroyed. On the right side the long process of the malleus had been almost entirely eaten away by the disease, and the remaining portion was bare and eroded. The ossicle was accordingly removed under chloroform, as in the previous cases, and the tympanic attic carefully cleansed. A considerable serous oozing followed for several days. At the end of a week, however, the ear was perfectly dry, and has remained so since. The operation was done four months ago, but as yet there are no signs of any regeneration of the membrane. In this case I have no accurate record of the hearing power previous to operation, as the child gave most unreliable answers, but judging from the mother's statements there seems to be some material improvement.

In considering the advisability of removing diseased ossicles it must be borne in mind that anything which tends to keep up suppuration from the ear is a source of danger not only to the hearing but also to the life of the patient. Absorption of putrid pus may take place into the systemic circulation, and set up general pyæmic symptoms, or the formation of localised abscesses in the cerebrum, the cerebellum, or the lungs. It becomes, I think, the duty of the surgeon to free the patient from this possible source of danger regardless, one might almost say, of the effect the operation may have upon the hearing power. The result "quoad vitam" should be more highly valued than "quoad functionem." It must be remembered also that in many of these cases of attic suppuration with perforation of the flaccid membrane the hearing power is by no means very poor. The results of the operation, however, show that the hearing power may improve in a remarkable way in many cases. In Ludwig's[12] analysis of 32 cases the hearing power was decidedly improved in 16, remained as before in 9, and was impaired in 3 cases; 4 cases did not undergo a re-examination. In my 4 cases there was improvement in all, especially in the second case. It must be borne in mind that the operation is not altogether free from risks. There is a danger of wounding the chorda tympani nerve in its passage through the middle ear. This accident happened in my first case, and was followed by some defect in taste for a few days. No special regard, however, need be paid to this accident, as the disturbance of taste is merely a temporary phenomenon. Facial paralysis may occur as the result of the operation. In 2 recorded cases in which this accident did occur, it disappeared after treatment by electricity. With due care these accidents may be avoided, and the operation will in most cases be found eminently successful.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

WESTMINSTER HOSPITAL.

SURGICAL CASES.

(Under the care of Mr. COWELL.)

THESE cases are illustrative of two of the rarer kinds of injuries met with in our casualty departments. The first, an incomplete dislocation of the foot at the calcaneo- and scapho-astragaloid joints, is one of the least common of the displacements of the foot: and although described in the text-books this account will bring more forcibly under the notice of our readers the signs which are found. The second case shows the occasional effect of machinery-amputation of part of a finger with rupture of the attachment of the tendon to the muscle, and not at the point of injury. This result of this kind of damage is illustrated in Erichsen's Surgery by plates taken from Morand's paper on the subject. A specimen of similar character was shown at the Pathological Society, in which, however, the tendon had been divided with the terminal phalanx of the thumb, and the nerves had been ruptured some inches from the wound.

Subastragaloid dislocation of the foot. (Reported by Mr. Powell, surgical registrar.)—G. R——, aged thirty-seven, a police sergeant, was admitted on Feb. 21st, 1891, with an outward dislocation of the right foot. He was ascending the steps of an omnibus, and when near the top slipped off, owing to the unexpected starting of the horses. He did not lose hold of the rails, but his feet came violently into contact with the ground, the hands sliding along the rail. Curiously, the foot (left) which first came in contact with the ground was uninjured, but the right sustained the rare accident above mentioned. The signs were obvious and the diagnosis easy. The foot was turned outwards with eversion, the external malleolus sinking into the hollow thus formed. The astragalus was in proper relation with the leg bones, but over its head the skin of the foot was very tightly stretched, so that its outline could be made out with great clearness. The scaphoid bone was drawn slightly beneath the outer part of the head of the astragalus, thus shortening the pre-malleolar portion of the foot. Mr. Cowell happened to enter the hospital a few minutes after the admission of the patient, and no time was lost in giving him an anæsthetic, when reduction was easily effected. Side splints with a foot piece were immediately applied. There was subsequently little swelling, although there was considerable ecchymosis. A week later a plaster-of-Paris case was applied to the ankle, and the patient was allowed to go home on March 5th, twelve days after the accident. He showed himself occasionally, and the plaster case was removed seven weeks later. The patient made an excellent recovery. Mr. Cowell remarked that the majority of the cases of subastragaloid dislocation which had been reported had been in the direction inwards This was a good example of the outward dislocation, and if the joint had given way above the astragalus the case would have been one of the ordinary Pott's fracture.

Avulsion of the terminal phalanx of the right thumb with the whole of the tendon and a portion of the muscular substance of the flexor longus pollicis attached. (Reported by Mr. Green, house surgeon.)—S. S——, an electrical engineer, aged nineteen, was admitted into Northumberland ward under Mr. Cowell on Dec. 17th, 1891. At 1 P.M. the patient was engaged in freeing a rope which had become entangled in a revolving shaft driven by straps, when his right thumb got caught in the rope, and the terminal phalanx, with the whole of the tendon and a portion of the muscular substance of the flexor longus pollicis attached, was torn away. The patient felt very little pain at the time of the accident, and did not faint or lose much blood. He came to the surgery about 1.20 P.M. suffering from the effects of shock, and was admitted at once, the arm being put in a boracic arm-bath. It was subsequently dressed with dry dressing, the forearm being thickly padded with wool over the origin of the muscle, and bandaged to a splint with thumb- and hand-piece. The temperature on admission was 99·4°, and did not rise above that point. There was no swelling at the point of laceration of the muscle.

On Dec. 27th the patient left the hospital with the wound granulating healthily. The tendon was eleven inches and a half in length, and to the upper six inches and a half muscular fibres were attached. The terminal phalanx was torn away at the joint; the skin, though jagged and uneven, was sufficient for the stump without surgical interference.

ROYAL INFIRMARY, NEWCASTLE.

A CASE OF POISONING BY BICHROMATE OF POTASH.

(Under the care of Dr. PHILIPSON.)

THIS substance, bichromate of potash, is so rarely taken, either by accident or design, that the account of a case in which a large amount of the drug was ingested, and in which the bad effects were successfully treated, is of unusual importance. Experiments on animals show that it possesses strong irritant properties, and a dose of two drachms has been known to prove fatal in the adult. In a case recorded by Mr. J. Stewart of Preston, a woman took a large dose of the bichromate dissolved in water, and died forty minutes afterwards. She became rapidly unconscious, with collapse,

Digitized by Google

purging, and vomiting; from the first the respiratory centre was markedly affected, and she appeared to die from respiratory failure. The appearances found on post-mortem examination were those produced by a corrosive poison. For the notes of this case we are indebted to Mr. W. Turnbull, acting house physician.

R. H——, aged forty-eight, labourer, was admitted into the Royal Infirmary, Newcastle-on-Tyne, under the care of Dr. Philipson, at eight o'clock on the evening of Sept. 11th, 1891, stating that he had swallowed a quantity of fluid used by cabinet-makers for purposes of staining furniture, and technically termed "red crystal." Having elicited from the patient the fact that the solution was prepared by dissolving a salt in water as well as a rather vague description of the salt itself, it was deemed probable that the poison employed was bichromate of potash. The patient occasionally worked for a master joiner in this city, and on the day in question, whilst in the workshop, he had partaken of the poison under the impression that it was cold tea, some of which stood in a can very similar in appearance to that out of which he drank. He shortly afterwards complained of the bitter taste remaining in his mouth, and on being questioned by his master as to which vessel he had used, the nature of his error became immediately apparent. As soon as it could be procured, about ten ounces of a solution of common salt were given to him, and with the idea of still further promoting or facilitating emesis he ate very freely some fat bacon which happened to be in the workshop at the time. This occurred at 6.45 P.M., and between that hour and his arrival at the hospital the symptoms had been as follows: An intermittent burning sensation over the gastric region, constant desire to vomit but inability to do so, and a general feeling of great bodily prostration; the bowels had also been opened twice.

On admission, beyond the fact that the man kept constantly moaning, but more from fear than from actual bodily suffering, and that the pupils were slightly less than normal, there were no obvious features in the case, either subjective or objective. The pulse was 80 and the respiration normal. Acting on the supposition already arrived at, the case was treated as one of irritant poisoning; the stomach pump was used, but only a small quantity of a viscid, frothy fluid was thus discharged, which, when treated with lead acetate, gave a slight yellow colouration. White of egg was next administered and the patient put to bed, warm bottles placed at the feet, copious draughts of milk, in which magnesium carbonate was suspended, being given internally. He now began to vomit very frequently and freely, some of the ejected matters being streaked with blood, but no other unusual features were noticeable in his condition until 9.30 P.M., when he complained of intense thirst, continuous burning sensation in the mouth and fauces and over the stomach; there was also decided tenderness detected on palpation of the latter area. Half an hour later these symptoms were further added to by a prolonged rigor. The temperature, which had previously been quite normal, quickly rose to 103°, the pulse at the wrist was almost imperceptible, and could not be accurately counted. He was given half an ounce of whisky, ice to suck, and milk with the addition of an equal part of soda-water. About 10.15 P.M. there ensued agonising cramps in the legs, which, commencing in the foot, passed up the thighs, but were of greatest severity in the calves of both legs; the arms were similarly but less markedly involved. Diarrhœa and an augmentation of the other symptoms—viz., vomiting, hæmatemesis, and cramps—serve to characterise the subsequent acute stage of the case. At 6 A.M. on the 12th the use of the magnesium carbonate was discontinued. At 8 A.M. an enema of starch and opium was injected, and this had the effect of allaying the tenesmus and diarrhœa. At 9 A.M. a mixture containing bismuth, opium, and sodium bicarbonate was ordered to be given every four hours. When seen by Dr. Philipson at 10 A.M., although the vomiting was less severe and distressing, the condition of the patient was yet eminently precarious, and justified the unfavourable prognosis given. Pulse 140; respiration 48; temperature 100°. Patient slept for about an hour in the afternoon. There was now a gradual cessation of all the symptoms, and in the evening thirst, faucial pain, and abdominal tenderness alone remained. Pulse 93; respiration 33; temperature 98°.

Sunday, Sept. 13th.—Morning: temperature normal; pulse 80; respiration 21. Evening: temperature normal; pulse 78; respiration 18. During the next three days the patient was only allowed milk or milk and soda-water. Recovery was very rapid, and a week later he left the hospital quite convalescent. Some of the liquid similar to that which he had swallowed was obtained from the workshop, and this when treated with lead acetate and silver nitrate gave the respective yellow and chocolate precipitates indicative of bichromate of potash.

As regards the amount of poison ingested, it was ascertained that the solution is made by dissolving one ounce of the salt in sixteen ounces of water, and as his master stated that the man had drunk not less than ten ounces of the fluid, he had therefore taken about 273 grains of the solid salt.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Tetanus as a Complication of Ovariotomy.

AN ordinary meeting of this Society was held on Jan. 12th, the President, Mr. TIMOTHY HOLMES, in the chair.

Dr. JOHN PHILLIPS communicated a paper on Tetanus as a Complication of Ovariotomy. After calling attention to contributions on this complication by Parvin and Olshausen, he related a case of the kind occurring in his own practice. The results of eighty-one inquiries addressed to various university professors in Europe, and sixty-seven in the British Isles, were given in the form of charts, and complete details of sixty-four cases were furnished. Many operators were found to have met with more than one case. The author, under these circumstances, had endeavoured to find out the reasons by tracing out the sites of operation, times of year, and the general surroundings of the cases. The various theories of the production of tetanus were discussed, and the possible complications in the operation and after-treatment which might be conducive to its onset. Allusion was made to recent bacteriological discoveries on the subject of the tetanus bacillus. A plan of treatment was recommended in consistence with these, and local treatment was thought to be of the first importance. He concluded: 1. That the operation of ovariotomy had elements in it which were conducive to production of tetanus by nerve irritation—i.e., tearing of adhesions and ligature of pedicle; but that tetanus in these cases did not deviate from the usual series of symptoms which were observed when it complicated other surgical operations. 2. That although some cases of tetanus arose *de novo*, and without necessarily the presence of sepsis, yet the usual manner of spreading was by contagion, and was aided by sepsis. 3. That although the "garden-mould" theory of causation was not established, yet that there was sufficient evidence to recommend avoidance of operating in a room recently plastered or situated near lately disturbed garden mould. 4. That on the first symptoms of tetanus arising, a strict local search should be made for irritating cause before proceeding to general treatment. 5. The folding over of a broad pedicle, which had already been ligatured, and then applying a second ligature, was not to be recommended. 6. That the only means of disinfecting instruments was by boiling them for at least an hour.

Mr. DORAN said that four of the cases which had been tabulated were not ovariotomies in the sense in which that word was commonly used. One was an oöphorectomy for fibroid, and if this condition was accompanied by menorrhagia the nerve shock after operating was usually very great. Another of the cases was a small myoma of the fundus uteri, with chronic ovaritis; a third case was one of removal of diseased tube; while in a fourth it was stated that the ovaries were indistinguishable, and it was really an incomplete operation for fibroid. As to the causation of tetanus, he had assisted altogether at 1287 abdominal sections, and had only twice encountered tetanus. One was Mr. Thornton's case, already published, where the operation was done in a windy farmhouse, and another was a case of Dr. Bantock's; the weather was changeable between frost and thaw, and it was windy. The patient one day complained of a draught on the cheek, and this was the beginning of the attack of tetanus. Statistics from abroad were not of much value till recently, for the nursing, as a rule, had been so extremely unsatisfactory. Looking over the cases which had been tabulated,

he observed that in one case the pedicle had been much pulled about, and this, he thought, might be a provocative cause. In other instances the omentum had been a good deal handled, but the latter would certainly not produce tetanus, for extensive adhesions of the omentum were being detached every day. A large number of women in the upper classes suffered wearying pains if they got a little flatulence or at the end of micturition; this was usually due to an adhesion of omentum to the pelvic organs. He would sum up the three principal causes of tetanus as meddling with the pedicle, draughts, and careless nursing.

Sir GEORGE HUMPHRY expressed his gratitude to the author for the careful way in which he had put the cases together. The first case which he himself had witnessed was in 1855, before the days of clamps and of antiseptic treatment. The case was an ordinary one, and on the eighth day he took his leave of the patient, as the wound had nearly healed. The same evening tetanus commenced and went on rapidly to a fatal termination. Another case was that of a lady aged fifty-seven, and though he had not actually operated he saw a good deal of the case; it was treated in the modern fashion by the intra-peritoneal ligature. The wound healed on the eighth day, and then symptoms of tetanus developed, the patient dying within twenty-four hours. In this last case antiseptic precautions were taken. Both these patients had perhaps been kept on too low a diet, and this may have predisposed to the development of tetanus. A good many cases of this affection had been under his own care, and he confessed himself unable to come to any conclusion as to the reason of the development of the attack in in any one of them. The original injury had for the most part been very trivial, such as the lash of a whip on the face &c. He had seen only one result from a cut between the thumb and forefinger, and he did not believe that there was any substantial ground for the common impression that an injury in this region was a fertile source of tetanus. He had seen nothing to suggest that garden mould might be a cause of tetanus, nor did he think that pulling about a wound ministered to its occurrence. He had never seen it follow when it might be most expected, such as after a badly lacerated wound with much damage to nerves &c.; but in all the cases it had supervened when one had no idea that such a result would happen. He had tried every variety of treatment, and he thought they all did more harm than good. He had kept the patient under chloroform for long periods, and this, together with morphia and other remedies, he thought was valueless; chloral and quinine perhaps did a little good. The sheet anchor of treatment was food, and when they could not swallow they always died. An infant, from the back of whose neck he removed a fatty tumour, developed a smart attack of tetanus, but it went on taking its milk well, and it ultimately recovered. He felt that the real nature of the disease was a blood poison, and that that was fast becoming the prevalent opinion. Perhaps something in the shape of an antitoxin might shortly be discovered to combat the poison.

Mr. HULKE, after referring to the uncertain opinions which had prevailed until recently as to the nature of this affection, thought that there was now ample evidence in favour of its being a specific infective condition. Dr. Phillips seemed to attribute it to a mechanical irritation, and at the same time he referred less confidently to the bacillary theory of its origin. The facts were that a bacillus easily recognisable had been discovered in tetanus; that pure cultures of this had been obtained and had been injected into test animals, with the result that tetanus was produced. Bacilli taken from human beings dead of tetanus had likewise produced tetanus in animals. These facts were so convincing that for him all other views fell to the ground. The long period of latency was curious, but the same thing was seen in hydrophobia. He related some cases which had come under his notice. In one a girl who was suffering from tetanus was said to have no wound or external injury, but over the left kidney was seen a healed scar, and from beneath it a large rough, ragged splinter of dirty wood was extracted. In another case there was a healed scar of the eyelid and conjunctiva, and at the back of the orbit was a nest of splinters of dirty wood. The poison seemed in this manner to lie dormant till some condition of the surrounding tissue permitted it to light up. He had tried nerve-section, nerve-stretching, amputation, eserine, &c., and he agreed that simple feeding seemed to be the best treatment; in the acute cases certainly nothing could be done. The last case that had come under his notice was that of a carpenter who had pricked his foot with a dirty nail. Carbolic acid was injected locally without result. He died, and from his blood a chemical substance was isolated, which he understood had produced symptoms of tetanus in animals.

Mr. LOCKWOOD felt that the last speaker had struck the true note, and that tetanus had taken a new position since Kitasato had separated the poison four years ago. He thought that it might be gathered from many of Dr. Phillips's remarks that sepsis as sepsis might produce tetanus; but it should be remembered that the bacillus of tetanus was constantly found with pus, and it speedily died in the presence of oxygen. It was an infective disease, the poison could be carried by dust, and this fact rendered the cases intelligible in which it was stated that draughts appeared to act as a cause. In one case he had investigated no bacilli were found in the tissues at the seat of inoculation. The spinal cord and arachnoid appeared to give better results for the purpose of inoculation than other tissues, and this affinity of the poison for nervous tissues explained many of the clinical symptoms. A spinal cord need not be fresh to give a pure culture, and as the tetanus bacillus would stand a high degree of heat, all instruments, in order to be thoroughly disinfected, should be boiled for some considerable time. He felt sure that the disease was never due to anything else but infection, and usually by means of earth. In one case the wound was inflicted by a stick when the child was playing in a garden; the earth of that garden inoculated under the skin of mice produced tetanus. He knew of two other cases in which the wounds had been caused by wood smeared with earth. He had tried treatment by oxygen inhalation; this ameliorated the spasms, but produced no other result.

Mr. MACNAMARA said that in Calcutta formerly tetanus was extremely prevalent, and it was observed to be most common under certain conditions of wind and temperature, especially a sudden fall of temperature with an east wind; the same influences had been observed to affect the spread of cholera and malaria. Since the introduction of antiseptic treatment in Lower Bengal the number of cases had remarkably diminished. He agreed in the importance of feeding, especially in the more chronic cases, and advocated the administration of full doses of chloral and bromide every evening in order to procure sleep.

Dr. PHILLIPS, in reply, said that his object was to collect all cases in which the ovaries had been removed, whether they were diseased or not. He felt that there was something in the theory that garden mould was indirectly causative of the disease, and believed that the only method of disinfecting instruments was by boiling

MEDICAL SOCIETY OF LONDON.

Cerebral Hæmorrhage—Galvano-cautery for Prostatic Obstruction.

AN ordinary meeting of this Society was held on Jan. 11th, the President, Dr. Douglas Powell, in the chair.

Dr. T. CHURTON of Leeds read the notes of a case of Cerebral Hæmorrhage, and demonstrated the anatomical conditions present by morbid specimens. A woman aged fifty-eight was admitted into the Leeds Infirmary on Sept. 18th, 1891, for right hemiplegia and hemianæsthesia without aphasia. On the 15th she had felt a sudden numbness in the left leg, and in about half an hour numbness in the right leg, which quickly, with the arm and face, became partially paralysed. On the 25th it was found that the left foot was completely anæsthetic; the right foot was then sensitive, a pinch producing exclamation and movement. She was quite conscious. There were signs of femoral phlebitis on the right side; the thigh was distinctly larger than the left. Reflexes: Plantar, slight on right, very brisk on left; patellar, sluggish on right, well marked on left. No ankle clonus. Hæmoptysis and other signs of pulmonary phlebitis appeared; the patient died on Oct. 2nd. A clot was found in the outer part of the left optic thalamus and fibres outside it; a quite dry, dark-red clot of the size of a walnut in the posterior horn of the left lateral ventricle, which was otherwise perfectly normal; no erosion of its surface and no staining; a dark clot in the right calloso-marginal fissure, overlying and slightly eroding the hinder part of

Digitized by Google

the gyrus fornicatus. The arteries were rather atheromatous. The brain was shown, with photographs, kindly taken by Dr. Turner at the Neuro-pathological laboratory of King's College. The bearing of this case upon the localisation of tactile sensibility in the brain was discussed, and it was shown that there were no local conditions which could have caused the anæsthesia of the left foot. The right thigh, hand, and cheek were insensitive; left, sensitive. He discussed four points in the case: 1. The occurrence of hæmorrhage in two hemispheres almost simultaneously. 2. The association of femoral phlebitis. 3. The mode of formation of the dry clot in the left lateral ventricle. 4. The anæsthesia of the left foot, which appeared to be due to lesion of the right gyrus fornicatus rather than of the motor area, because (*a*) no paralysis of the foot was observed; (*b*) staining and slight erosion were seen upon the gyrus fornicatus, and none upon the convolutions above the clot; (*c*) in a case (published by himself) of tuberculosis of the same motor area, causing rhythmic muscular movements, there was no pain or other observed sensory disorder.—The PRESIDENT inquired if the vessels in this case had been found to be notably diseased. The presence of phlebitis in so many directions was remarkable. He asked what was considered to be the connexion between the phlebitis and the cerebral hæmorrhage, and if the latter condition had been produced through the former by way of embolism.—Dr. TURNER said that the case, of interest to the general physician, was especially so to the neurologist. He knew of only one other case at all similar to it, which was recorded by Dr. Savill in the last number of *Brain*. It was that of an old man who had hemianæsthesia and trophic changes on the left side. He got better of this, and then three years later he had another attack, of which he died. At the post-mortem examination a cyst was found in the right gyrus fornicatus, extending into the quadrate lobule. Both these cases corroborated the conclusions which had already been arrived at as the result of experiments on monkeys—namely, that if the falciform lobe were destroyed, anæsthesia of the opposite side would ensue. Munck and others abroad held that the Rolandic area comprised the centres of common sensibility, while Ferrier and others in this country maintained that common sensation had a special centre in the falciform lobe. The case related certainly strongly supported the latter view. In the case of Dr. Savill trophic changes had been noted, but they were not present in the instance under discussion.—Dr. CHURTON, in reply, said that at the necropsy a clot was found in the right iliac vein. The left posterior tibial artery was examined and also the femoral, but nothing was found there to account for the anæsthesia of the foot, and the good condition of the superficial reflexes showed that the nerves had not been destroyed. He thought that the phlebitis and hæmorrhage were due to a common cause—the circulation of some irritant in the blood, which set up inflammation both in the arteries and veins; the headache was possibly to be accounted for in the same way. He had not noticed any trophic changes, but then the patient only lived three weeks from the onset of the disease. Judging by analogy from the spinal cord, he thought that trophic changes would be more likely to follow if the damage were to a part of the motor tract.

Dr. CHURTON likewise showed a patient in whom he had diagnosed the existence of a gumma, which extended from the middle of the pons Varolii to the lower part of the medulla oblongata on the right side. The patient had presented paralysis of all the nerves, from the fifth to the twelfth inclusive, but the motor part of the fifth had never been involved. There was marked atrophy of the left half of the tongue and of the left sterno-mastoid and trapezius. He was slowly but distinctly recovering from below upwards under treatment, the fifth nerve being now entirely cured and the seventh partially so. Two years ago he was quite well, and he then lost a large amount of blood from piles; he had had syphilis years ago, and the loss of blood, coupled with deprivation of food, had probably caused the gummatous inflammation to develop. The first symptom noticed was a loud tinnitus aurium, which disappeared after incising the membrana tympani. As soon as the incision healed the tinnitus reappeared; but a fresh incision, together with regular inflation of the Eustachian tube, had rid him again of this trouble.

Mr. BRUCE CLARKE read a paper on the Radical Cure of Prostatic Obstruction by the Galvano-cautery. After briefly discussing the various surgical procedures which had been recently employed for the relief of enlarged prostate, the writer pointed out that there were many slighter conditions which, while they did not merit so extensive an operation as supra-pubic removal involved, were yet quite as annoying and inconvenient to their possessors. Indeed, whether the prostate was very large or not, the actual obstructing portion of it was exceedingly small, and hence the success which might be obtained by the removal of only a small portion of a large mass. He then went on to describe the galvano-cautery of Bottini, and the method by which it was employed, as well as the general results which it yielded, after which notes were read of four cases which had been under his care. From these it appeared that out of four who had suffered from enlarged prostate for some time, and who came under his care with a considerable amount of residual urine in their bladders, all were able to micturate without difficulty, and only one of them had still any residual urine in his bladder. In other words, out of four patients so treated, three were absolutely cured, and had remained so for a period varying from three to six months after operation, and the remaining case was much better, and still improving.—The PRESIDENT asked if any disagreeable cicatricial results had followed, and whether the use of a catheter was necessary in consequence.—Mr. HURRY FENWICK said that he had used this method of treatment both at the London Hospital and at St. Peter's Hospital. He would discuss it under the heads of practicability and applicability. As to its practicability, it was very difficult to get the instrument to work, for it required such a powerful battery to heat it. Two large storage accumulators at least were necessary, and the Italian instrument was so short that it was not at all easy to get it into position. As to its applicability, in very few cases could it yield a good result. In one instance, after use of the instrument, he was obliged to cut down supra-pubically and shell out the middle lobe of the prostate. It was, indeed, only good for the ridge-like form of obstruction, which could be better treated by a perineal incision and division with a blunt knife. Statistics showed that 90 per cent. of the prostatic obstructions were due to middle lobe enlargement, which would not be reached by this instrument, while in only 10 per cent. was the bar obstruction present.—Mr. SWINFORD EDWARDS said that he had had no personal experience of this method, but it appeared to be a good one if it could restore natural micturition. He inquired of the author if he had tried electrolysis puncture through the rectum, which was said to cause shrinkage of the prostate. The cases seemed to have been well selected, for the urine was normal in all. He feared that this operation was likely to set up cystitis and inflammation spreading backwards. He himself had used a modified prostatome, which punched out a portion of the gland. He obtained an immediate good result, though the benefit was only temporary. The supra-pubic operation was undoubtedly a serious one, and as it was usually demanded in broken-down old men, it should never be lightly undertaken.—Mr. BUCKSTON BROWNE said that the ordinary prostatic case was usually such an exceedingly simple one to manage, that we should be very careful before we rushed to new methods of treatment. He regarded supra-pubic prostatectomy as dangerous, and only to be resorted to in extreme cases. He admitted, however, that there were indications for its employment. The operation of Bottini was enticing from its apparent simplicity, and was therefore apt to be employed in unsuitable cases. A man who had only just begun to use a catheter should certainly not be submitted to such an operation. The fourth case appeared to him to be one of bad stricture together with atony of the bladder; he thought it probable that after treatment of the stricture the bladder would have recovered power independently of Bottini's operation, and the good result therefore ought not to be credited to the latter. It should not be forgotten that it was quite possible for a man to regain power absolutely over his bladder after having lost it for a considerable time. He related an instance in which a gentleman, being unable to relieve his bladder, was left afterwards in a condition of retention for sixty hours. Three pints of urine were then drawn off, but for six months afterwards he could pass no urine except by catheter. He was now, however, able to empty the bladder entirely by natural effort. He agreed with Mr. Fenwick that the majority of cases of prostatic obstruction were due to middle lobe enlargement, for which this procedure would be of no avail; in such cases incision from the perineum or urethra

Digitized by Google

met with but trifling success.—Mr. CLARKE, in reply, said he had carefully selected his cases. He agreed that, in cases of middle lobe or of irregular enlargement, if any treatment beyond catheterism were indicated, then the supra-pubic operation should be done; but he had not of course advocated Bottini's method for these. One could not expect to get a good result unless the bladder were healthy, and he doubted if the operation were more dangerous than lithotrity in skilful hands. He admitted that an instrument requiring a lighter battery power could be constructed, and would be more convenient; but that did not touch the question of applicability of the method. He held that the question of frequency should not be decided by an appeal to museum specimens; the only statistics of value were those of the post-mortem room.

CLINICAL SOCIETY OF LONDON

Gout of Penis.—Trephining for Hæmorrhage from Middle Meningeal Artery.—Gastro-enterostomy and Jejunostomy.

AN ordinary meeting of the Society was held on Jan. 8th, the President, Sir Dyce Duckworth, in the chair.

The PRESIDENT first alluded in a few touching words to the loss the Society and the profession had sustained by the comparatively sudden decease of Mr. Berkeley Hill.

The report of the committee appointed to ascertain the period of incubation of various diseases was then presented and received.

Sir DYCE DUCKWORTH gave the clinical history of a case of Gout of the Penis. A man aged forty-two, a glass cutter, was admitted into St. Bartholomew's Hospital with gouty arthritis, involving several joints, including those of the great toes. There was moderate pyrexia. The patient had been discharged from a cavalry regiment twenty years previously on account of hernia. Since then he had led a sedentary life, and drank about two pints of beer daily. Sixteen years ago he suffered from lead colic, and was in St. Bartholomew's Hospital for treatment. He was occasionally subject to attacks of articular gout, and inherited the disease from his father. Five days before admission he was awakened by sudden pain in the right wrist and right great toe-joint. The following day he awoke with pain in, and firm erection of, the penis. This continued up to the time of admission. Three days later the left great toe-joint was attacked by gout. The various thoracic and abdominal organs were found healthy. The urine was acid, sp. gr. 1022, and void of albumen. The penis was erect and tense, distressingly painful and turgid. No points of hardness were found in its course. The testes were natural. There was no pain or swelling in the perineum. There was pyrexia, with a temperature varying from 99° to 102°. Aperients and salines with colchicum were administered, and a light diet. The priapism persisted steadily, uninfluenced by internal treatment, by sedative suppositories or lead and opium lotion. A cage had to be placed over the abdomen to prevent impact of the bedclothes. Micturition was painful, and soft catheters had to be passed. From time to time fresh articular attacks of gout occurred in various joints with slight rises of temperature. Priapism persisted for twenty-one days without intermission, and gradually subsided with general amendment of all the symptoms. The noteworthy points in the case were—first, the gouty inheritance; secondly, enforced sedentary habits, with exposure to lead impregnation, and the habitual drinking of beer. The extreme rarity of the case was commented on. While acute gouty inflammation was shown to be not infrequent in the bladder, prostate gland, and testes, gout of the body of the penis in this acute form was practically unknown, and the author had never heard of a similar case. The pathology was believed to be thrombosis of veins in the corpora cavernosa, with some inflammatory condition of the trabecular structure, return of blood being mechanically prevented during the blocked condition of the parts. Smaller thromboses of this nature had been previously noted, but not leading to painful persistent priapism, and entailing the presence of small knots readily perceptible in the body of the penis, which slowly or imperfectly disappeared. Priapism was sometimes met with in elderly men as the result of a very acid condition of the urine, and was readily removed by alkaline treatment. The author classified the condition described as amongst the rarer forms of gout, of which gouty parotitis was another example.—Dr. ORD thanked the author for the record of such a rare clinical condition, which in an acute form he had never met with.

Mr. BLAND SUTTON read notes of a case of Fracture of the Skull complicated with Hæmorrhage from the Middle Meningeal Artery in which trephining led to a successful result. The patient was conveyed to the Middlesex Hospital in an insensible condition, due to falling upon the pavement and striking his head when drunk. Soon after admission the right arm and leg became completely paralysed. From the history of the case Mr. Sutton came to the conclusion that there was an extravasation of the blood due to injury of the middle meningeal artery. Acting on this opinion, the left side of the skull was trephined. A very large clot of blood was found between the dura and the bone. In order to secure the torn artery it was necessary to remove bone freely. By means of an electric search light a fissure in the bone was found to run from the left limb of the lambdoid suture downwards into the tympanum and across the petrous portion of the temporal bone. At this spot the dura was lacerated and the sub-dural space opened. After the operation motor power returned in the paralysed limbs, cerebro-spinal fluid escaped during four days, but the patient quickly became conscious, and made an uneventful recovery.—Mr. CHARTERS SYMONDS said he had performed operations on three of these cases. The first of these had been already published in the Transactions, and was similar to that described in that the bleeding came from a deep source far forwards, necessitating the removal of much bone; the hæmorrhage was controlled by fixing forceps on the bleeding point. The case proved fatal from a limited meningitis round the site of operation, which he thought was due to prolonged exposure and to the use of the spray. Both his other cases terminated successfully. In one the patient, a man, was knocked down by the blow of a crane. He was at first quite conscious, and complained of intense intracranial pain. In an hour and a half he became unconscious, and had universal convulsions. He recovered after trephining. The last case was that of a boy who was brought into the hospital after an accident to the head. He was quite sensible, but in the course of two hours became unconscious, and almost dead. Artificial respiration was carried on, the skull being trephined meanwhile. He soon rallied, and afterwards made a good recovery. During the operation compression of the carotid was practised, and continued for four hours afterwards; this materially checked the hæmorrhage.—Mr. GODLEE said he had operated on three or more cases, and he had seen several. None of those he had dealt with had been successful, and the reason for this was that they were usually left so long before operation that the cerebral tissue had lost its power of expansion after removal of the clot. His opinion was that instances of this lesion were not very rare.—Mr. SUTTON, in reply, said that when he removed the clot the dura and brain were nearly an inch and a half from the surface, but twelve hours afterwards complete expansion had taken place.

Mr. BOWREMAN JESSETT gave the details of five cases on which he had performed Gastro-enterostomy for pyloric carcinoma, and two cases of Jejunostomy on patients who were suffering from carcinoma of the cardiac end of the stomach. Of the five cases of gastro-enterostomy, three had recovered. One case which was shown at the Society in April, 1891, and on whom the operation had been performed in April, 1890, was well at the date of reading the paper, and able to eat and digest ordinary food. A second case which had been operated on fifteen months ago was also well. In neither of these cases had the disease materially increased in size. The third case died nine months after the operation, having lived in comparative comfort until the time of her death. Of the two cases which had died, one succumbed because feeding had not been begun early enough, the patient dying of exhaustion; the other died of septic peritonitis. Since the writing of this paper, Mr. Jessett reported that he had operated on the two other cases, one dying from collapse after the operation, never having rallied from its effects, and the second was a case of combined pylorectomy with gastro-enterostomy, which was shown at the Society in October, having been operated on in the previous July. The patient reported himself now as being well and in the enjoyment of fairly good health. In all these cases the operation was performed by means of decalcified bone-plates. The two cases of jejunostomy were

Digitized by Google

both performed in men who were in a terrible state of collapse, pain, and emaciation at the time of operation. Both operations were successful, one man living in comparative ease for nine months, during which time he was free from pain and able to feed himself through the fistulous opening. The other man, although the operation *per se* was successful, succumbed six weeks after from exhaustion. These two operations were performed by a novel method suggested by the author, which was fully described.—Dr. BURNEY YEO said that these cases were very interesting to physicians. It should be remembered that some cases of scirrhus of the pylorus ran a prolonged course under suitable treatment, living in tolerable comfort for many years, and this should make physicians hesitate before recommending operation. In one instance from the commencement of symptoms to the termination of the case seventeen years elapsed, and in another twenty-two years. Success depended on suitable feeding, nothing being given but what the stomach could readily absorb, and under these conditions the patients would often rapidly rally. He held that the stomach rather than the rectum should be trusted for nutrition in these cases. He had seen the greatest benefit result from the persistent administration of creasote, and also from courses of Carlsbad water.—The PRESIDENT concurred in the value of palliative medical treatment in such cases. But if it were found that in spite of careful feeding the patient was losing ground, there could be no doubt that operation should be done at once. It was remarkable how varying was the susceptibility to cancer of various individuals, some being particularly vulnerable, while others apparently possessed the power of resisting its incursions. He asked if in the fatal cases the diagnosis of cancer was confirmed post mortem, and what operation the author would do in a case of closure by malignant growth of the lower part of the œsophagus.—Mr. JESSETT, in reply, said he had never seen a case of pyloric cancer last so long as some of those quoted. He strongly suspected that the diagnosis might be in error, and that they were instances of pyloric fibrous stricture which afterwards underwent malignant degeneration. He agreed as to the value of suitable diet in preserving strength and nutrition. Three of the cases he had related had been under treatment for a long time, and had been going steadily down hill; the last, indeed, never rallied from the operation, which had been postponed too long. He advocated early operation, as then there was a chance of not only doing gastro-enterostomy but pylorectomy as well, if the case should prove one suitable for extirpation of the growth. One of his fatal cases proved to be non-malignant fibrous stricture. In a case of cancer at the lower end of the œsophagus he would do gastrostomy, with the use of Senn's plates.

Reviews and Notices of Books.

Surgery. By C. W. MANSELL MOULLIN, M.A., M.D. OXON., F.R.C.S., Surgeon and Lecturer on Physiology to the London Hospital; formerly Radcliffe Travelling Fellow and Fellow of Pembroke College, Oxford. London: J. & A. Churchill. 1891.

IT is impossible to read this work without realising that certain circumstances may tend to raise a prejudice against it. A volume of over 1400 pages is of necessity very cumbrous, and the reading has been made difficult by the disproportionate margin to the text. This cannot fail to act unfavourably on the mind of a reviewer and to damp the ardour of a student. Of a total of 495 illustrations only 152 are original, while 132 are Mr. Bryant's and 63 are Ferguson's. In a new edition of the list of illustrations the source of the borrowed illustrations is given, but it is not indicated in the text as it ought to have been. We cannot help feeling that to rely so largely as this upon the work of others, and particularly to use for one surgical text-book woodcuts prepared for a previous one, is most undesirable.

The work is designed as a text-book for students, and as such is an ambitious attempt to rival or surpass those of Erichsen, Bryant, and Holmes. The author has displayed great courage in undertaking such a task, for it must be confessed that he is heavily handicapped in the contest. The writers we have named had all had a large experience in the practice and in the teaching of surgery when they published their works, while it is Mr. Mansell Moullin's good fortune to be in a position to anticipate such an experience. And it must be confessed that experience is the highest of all qualifications for the writer of a text-book, and we cannot say that we find evidence in the book before us that other excellent qualities can compensate for its want. Mr. Mansell Moullin has shown great industry, has made good use of surgical literature, and has utilised the researches, writings, and experience of others. The teaching of the book is in general harmony with that of British surgeons, and students will find it a safe guide. The writer's object appears to have been to give an epitome of general surgical knowledge, and not to advance original or the most novel teachings, and in that he has been well advised.

The Book of Climates. By D. H. CULLIMORE, M.D., M.R.C.P. Lond. and Dub. London: Baillière, Tindall, and Cox. 1890.

THE object of this work, we are informed in the preface, is "to give a concise, clear, and useful account, and one which will be acceptable alike to the profession and the public, of the climates of the different countries of the globe, their salubrity, health resorts, mineral springs, and prevailing diseases." In attempting to accomplish these objects within the limits of a small volume of 266 pages, the author has essayed a practically impossible task, and has condemned himself to inevitable incompleteness and superficiality. He seems conscious of this himself, remarking that "the greatest difficulty encountered has been to keep it within the limits prescribed by the publishers and the needs and purchasing capacity of the profession and the public, and to render the descriptions at the same time interesting, intelligible, and useful." Nevertheless, as a slight sketch of the great topic of the world's climates and their influence on health and disease, Dr. Cullimore's work possesses some considerable merits. A very large amount of information is packed into the narrow limits of space allotted to the author. There is no verbiage or padding, and the writer presents his facts in the main accurately and in a readable form. We have, however, noted some curious errors. Thus at page 197 we find the extraordinary statement that "at Cairo, which is a dirty, crowded, low-lying city, the death-rate is about 30 per cent." (*sic*)! The actual death-rate of Cairo during the last seven years, including one cholera year, has been 21·8 per 1000 among Europeans and 46·5 per 1000 among the natives. At page 18 we are informed that "in Switzerland, Austria, and the south of France places ..... above 4000 feet are generally exciting, and often wet, variable, disagreeable, and harsh." This statement requires much qualification. Such statements as that "Penzance possesses the most equable climate in the world" (p. 64), and that "Homburg is perhaps the most popular and amusing bath in Europe" (p. 126), are certainly at least open to serious question. Such errors or questionable statements are, however, exceptional, and though calling for correction or modification, do not seriously detract from the general accuracy of the information presented by Dr. Cullimore.

It will be seen that the author aims at giving a bird's-eye view of *all* the climates of the world without regard to the special merits which some of them possess as sanatoria. The point of view thus assumed is that of the physical geographer rather than of the physician and medical climato-

Digitized by Google

logist. It may be questioned whether this is a convenient or practically useful way of handling the subject. It entails relatively long descriptions of countries of no importance therapeutically, while some of the most valuable resorts are too briefly dismissed. Thus Dr. Cullimore devotes five pages and a half to Burmah and adjacent countries, and about the same space to the West Coast of Africa, the Soudan, and the Congo; while Egypt receives rather less than two pages, Algeria a little more than two pages, and Madeira and Tasmania about half a page each. This is a serious detraction from the value of the work regarded as a guide to the profession or to patients seeking a new climate on the ground of health. This plan has the further drawback that it leads the writer to give prominence to mere geographical or physical facts, while the difficult but interesting and vitally important problems of medical climatology receive relatively scant attention. In this department, however, as far as he goes, Dr. Cullimore is, in the main, a safe guide. He appears to have no prejudices and indulges in no hyperboles, and his hints on the therapeutic applications of the various climates, though brief and inadequate, are rarely much at fault.

Dr. Cullimore writes from a considerable personal experience of foreign countries and climates, and his book is a practical one. We cannot help wishing, however, that he had allowed himself wider limits of space and given us a really adequate account of the interesting and important topics with which he deals.

OUR LIBRARY TABLE.

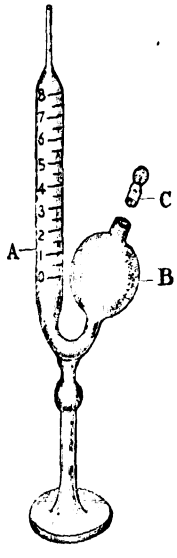
Abdominal Surgery. By J. GREIG SMITH, M.A., F R S E., Surgeon to the Bristol Royal Infirmary, Lecturer on Surgery, Bristol Medical School. Fourth Edition. London: J & A. Churchill; Bristol: J. W. Arrowsmith. 1891.—The fact that in four years as many editions of this work have been called for, and that the present edition is being translated into French, German, and Italian, is the best possible evidence of the high value attached to Mr. Greig Smith's monograph both at home and abroad. The original volume of 600 pages has grown to one of 800 pages, and it has been found necessary to omit the Bibliography, which had grown unmanageably large. But an "Index of Authors," referred to in the text, has been introduced. The book has been brought well up to date, new operations are noticed, and the latest results of treatment are given. The inaccurate term "laparotomy" and the clumsy one "abdominal section" are replaced by "cœliotomy," which was first proposed by Harris of Philadelphia This seems the best suggestion that has yet been made, and it would save confusion in the future if surgeons would agree to use it.

Report of Experiments now being pursued in the Bacteriological Laboratory of the Academy of Natural Sciences of Philadelphia. By SAMUEL G. DIXON, M.D. Philadelphia. 1891.—In this short note Dr. Dixon gives the results of a series of experiments on the growth of tubercle bacilli on special media, and also on the treatment of tuberculosis by subcutaneous injections of dilute sulphuric acid and formic acid. He thinks that the tubercle bacillus loses its virulence in a certain degree when it is cultivated continuously on artificial media, and gives the result of a series of inoculations of such material into young dogs; he hints that the injection of glycerine into the body may interfere with the action of the poisonous products of the bacillus. The report, however, is incomplete, and is apparently only a tentative one.

On Certain Conditions that Modify the Virulence of the Bacillus of Tubercle. Proceedings of the Royal Society vol. xlix. By ARTHUR RANSOME, M.D., F.R.S.—In this short paper a series of observations are given to prove that fresh air and light and a dry, sandy soil have a distinct influence in diminishing the virulence of the tubercle bacillus; that darkness may interfere with this disinfectant action, but that the mere exposure to light in otherwise bad sanitary conditions does not destroy their virulence. The data on which these conclusions are based are somewhat scanty—a fact which is acknowledged by the author, who, however, promises a series of further observations, and also a note of the examination as to the pathological conditions met with in the specimens he obtained.

Outline of a Course of Lectures on Human Physiology. By ERNEST ALBERT PARKYN, M.A. London: Allman and Son. 1891. Pp. 167.—In the compass of a very small book Mr. Parkyn has managed to condense a considerable number not only of physiological, but of histological, anatomical, and chemical facts. In the compass of less than 200 pages it is not possible to give more than an outline of the mode in which the various functions of the body are performed; but what is here given is at least correct, and the treatise might well be used in schools of either sex as a reliable exposition of the main facts in physiology.

The Philosophy of Clothing. By W. MATTIEU WILLIAMS, F.R.A.S, F.C S London: Thomas Laurie, Paternoster-row. 1890.—We find in this little book a series of well-written chapters on the why and wherefore which ought to regulate our choice of clothing. The experiments of Baron Rumford on heat conduction and evaporation, which form the text of these remarks, are explained in brief detail and with admirable clearness. Not a few suggestive particulars, moreover, have been added by the author's own thoughtful originality. His appeal for woollen or other porous underwear, his dislike of the warm and close overcoat, his advocacy of down as a wholesome but still untried clothing material, will each and all bear the test of skilled criticism. Let us not forget to notice a recommendation of dark underclothing for the tropics, founded on Surgeon-Major Alcock's theory of heat-stroke by cutaneous impression. After a careful perusal we have no hesitation in saying that the reader will find in these pages much to instruct and entertain him, much that he can safely endorse, and little occasion for serious dispute.



We have before us the *Veterinary Journal* and *Annals of Comparative Pathology* for November and December. In the former number is an account of some recent experiments with "mallein" made by Mr. Leonard Pearson, V.S., V.M.D., Pennsylvania University. This mallein is a filtered broth and glycerine culture of the glanders bacillus. He finds that in those cases in which repeated injections were made the mallein had not the least deterrent effect on the development of the glanders process. He believes, however, that this substance will be useful as a diagnostic in doubtful cases of glanders. The same author contributes a short article on recent foreign investigations of swine disease, from which he argues that there is but one swine pest in America — that is, that hog-cholera and swine-plague are the same. Reports of meetings, class lists, and introductory addresses make up the remainder of this number. In the December number Mr. E E. Bennett, F R.C.V.S., A.V.D., follows up Mr. Pearson's notes, and gives records of a number of sets of experiments from which he also argues that mallein may be useful as a diagnostic agent. Professor M'Fadyean continues a most interesting article on Tuberculosis, and Professor Fred. Smith of the Army Veterinary School, Aldershot, who has recently protested against the overloading of our cavalry horses, has an exhaustive paper on Veterinary Hygiene. Reports of the various colleges and veterinary associations complete this number.

New Inventions.

A SIMPLE INSTRUMENT FOR THE QUANTITATIVE ESTIMATION OF SUGAR IN THE URINE.

DR. EDGAR GANS of Carlsbad has recently called the attention of the profession at Berlin to a simple instrument for the quantitative estimation of sugar in the urine which is particularly adapted to the wants of the general practitioner, on account of its accuracy and easy manipulation. It consists of a U-shaped glass tube about six inches high, the longer leg (A) of which is graduated, as the annexed sketch shows, the shorter leg (B) terminating in a glass bulb, on the extremity of which fits a glass stopper (C).

The sides of the bulb and of the stopper are pierced in corresponding diameters by two fine holes, so that the exit of air can be prevented by a slight turn of the latter. To use the instrument, first mix in a flask 10 cc. of the urine to be examined with 90 cc. of clean water, and shake up with a piece of yeast about the size of a coffee bean till there are no longer fragments of yeast floating about in the vessel. Then pour 10 cc. of this mixture into the bulb (B), and adjust the stopper (C) so that the holes in the bulb and stopper coincide. Now tilt the tube to the left, so that the level of the fluid in A corresponds with the zero on the scale, and by a slight turn of the stopper shut off communication with the atmosphere. Leave the instrument in an ordinary room-temperature (about 65° F.) for eighteen to twenty hours, and, fermentation going on, the liquid in tube A will rise from the point 0 in proportion to the amount of carbonic acid given off—that is, in proportion to the amount of sugar in the urine. The instrument is so graduated that the points on the scale correspond to the percentage of sugar, so that if the fluid in A rises to 2·5 the percentage of sugar is 2·5. After repeated experiments Dr. Gans found that in accuracy it almost equalled the method of polarisation, while in cases of the simultaneous presence of sugar and albumen in the urine it could be used when the polarimeter could not. The instrument can be obtained at a nominal cost from Fiebig, Alexandrinenstrasse, 27, Berlin.

L. M. SCOTT, M.A., M.B., D.P.H. Aberd.

THE GEM FILTER.

FOR the removal of suspended matter in water this little filter answers admirably. On passing through it a sample of turbid and dirty water, which failed to deposit even after several days, a perfectly clear and bright filtrate was obtained. The gem filter, made by the Gem Water Filter Co., 21, York-place, Leeds, consists of a plated metal cylinder about two inches in diameter and two inches in length, provided with a screw thread at either end, so as to make it convenient for attaching to the ordinary supply tap. The cylinder contains pure coarse quartz, bounded top and bottom by a small sieve of fine mesh. By reversing the filter any sediment that may have accumulated can be removed. Quartz serves as an efficient filtering medium as regards the removal of suspended matter, but other media, such as well-prepared coke, might be used with equal effect, and with the additional advantage that it would also remove a part at least of the organic matter in solution, as well as, according to Frankland's experiments, certain low forms of life.

AN EXPERIMENT IN SEWAGE IRRIGATION.

MEADOWS irrigated by the town sewage to the extent of some eight acres have been worked at Crieff for at least sixty years: part on the Broich estate, where the ground was gravel and flat; part on the Crieff estate, on moorland with a steep slope. The grass was a coarse meadow grass, mixed with many water plants and weeds. The grass was cut and sold.

In 1870, Dr. Andrew Smart of Edinburgh writes, a new water-supply was introduced to Crieff equal to 450,000 gallons per day. After some years it was found that the small meadows were drowned by so much water of a depth equal to twenty feet a year. At Broich the sanitary state of the dwelling-houses was seriously injured, and the irrigated area was reduced, and the sewage run to waste into the river Earn. On the Crieff estate most of the sewage was run to waste. It was then found necessary to investigate the question with a view to utilise such a large quantity of weak sewage. Crieff is fortunately situated on a hill with a southern exposure. The ground is naturally steep, and very favourable for drainage and irrigation. In fact, few towns have the advantages of a south aspect, with hills to keep off the north and east winds, extensive views, and a large area of land of several hundreds of acres, all at a level suitable for irrigation. After mature consideration, it was decided to carry out an entirely new scheme.

Instead of trying how much sewage could be run on an acre, it was determined to try how thin the sewage could be spread, and over how large an area it could be used. Some sixty acres were available to treat about one-fourth of the sewage. This sewage includes the rain water. Two sewers were laid, one a high-level, six inches in diameter, and a low-level sewer twelve inches in diameter, as a gradient of only 1 in 200 was obtainable, and this low sewer was liable to floods. These sewers are so arranged as to have a valve for irrigating each field quite independently of the others; the sewers are at least three feet below the surface, and any field can be irrigated at pleasure. The fields were all tile-drained some forty years ago. The soil is a poor, moor soil. The old meadow system of cutting the grass in summer was entirely given up; none of the grass is cut. The fields are laid down with fine pasture grasses; the sewage is distributed over the surface by catch-water gutters cut in the sod. During summer the grass is grazed by milk cows and other cattle; in winter sheep graze on it. It is found best to shift the sewage after a week; there being such a large area available, this is easily done. A discharge of one gallon per square yard per day for a week together produces a good result; it is then shut off that field and put on to another field; a field should not have sewage run on for more than a week continuously. It is found that weak, thin sewage is easily carried and distributed. The surface gutters require raking out occasionally. The financial result is satisfactory, and no difficulty has been experienced in the working. Turnips have been successfully grown by running sewage continuously for three months, but turnips have very little effect in purifying the sewage. The drainage from turnips and all other crops should be run over pasture, which alone has the power of extracting manure out of water.

ORPHAN WORKING SCHOOL, HAVERSTOCK-HILL.—These schools, which usually have over 500 children in occupation, have had to be closed and the children removed owing to defects in the sanitary condition of the buildings, and the Estates Committee instructed their architect, Mr. Chas. Bell, to prepare plans and specifications for putting matters in order. Mr. Bell prepared two schemes, one for improving the existing sanitary arrangements in their present positions, and another for building detached sanitary blocks. As either of the schemes was likely to entail considerable expense, it was decided to consult some sanitary expert on the matter, and Mr. Edward Tidman, C.E., F.S.I., of Westminster, was instructed, and has just reported to the committee, advising the adoption of the separate detached blocks, with certain modifications. Mr. Tidman's report was adopted, and the architect instructed to obtain estimates strictly on the lines of Mr. Tidman's report and recommendations, and it is proposed to carry out the work without delay.

THE LANCET.

LONDON: SATURDAY, JANUARY 16, 1892.

THE DEATH OF THE DUKE OF CLARENCE AND AVONDALE.

IN common with every subject of the QUEEN the members of our profession have been profoundly saddened by the severe blow that has fallen on the Royal Family in the death of the eldest son of the Heir Apparent after an illness of very brief duration. The circumstances of this sad bereavement are especially painful in the cutting off of the life of one who was about to enter on a new phase of domestic happiness, with such brilliant prospects. This is not the place or the occasion to dwell on the vanity of earthly things or the bitterness of unfulfilled hopes; but we may at least tender to their Royal Highnesses the Prince and Princess of WALES and the members of their family our heartfelt sympathy; and especially should we include in this tribute of condolence the name of the young Princess who has been bereft of him to whom she had plighted her troth, and with whom she might one day have shared the highest station in the realm. The English nation has during the present reign often evinced the depth and tenderness of its affection for Her Majesty and her family, and since the fateful December, thirty years ago, when the greatest blow that woman or Queen could suffer was inflicted upon her, there have been several occasions on which this bond of sympathy has been made manifest. Never, indeed, since the death of the Prince CONSORT has such universal sorrow been expressed throughout the land, its intensity being, perhaps, heightened by the suddenness with which the tidings of the fatal illness of the young Prince became known.

His Royal Highness the Duke of CLARENCE AND AVONDALE was attacked by influenza on Thursday, Jan. 7th, but first felt really ill on Friday, Jan. 8th, when he was unable to attend the birthday dinner given in his honour. On Saturday evening, Jan. 9th, a patch of pneumonic consolidation was discovered at the base of the left lung; there had been no distinct rigor, but his Royal Highness appears to have had some shivering on Thursday, the 7th. On Sunday morning, Jan. 10th, dulness on percussion and tubular breathing were present up to the level of the dorsum of the scapula, and in the afternoon as high as the spine of the scapula on the left side, while at the right base also these signs had appeared, and were found up to the angle of the scapula. No crepitation was heard at any time, and the consolidation did not extend far on the lateral aspect of the chest. The temperature was 103·4°; the pulse about 90 and of good character; the respiration 30; and the intellect was perfectly clear. During the night of the 9th the Prince was very restless; on that of the 10th there were snatches of sleep, and at one time the temperature fell below 102°. No material change took place in the condition of his Royal Highness on Monday, the 11th, but there was copious expectoration of yellow colour, occasionally blood-stained, not very viscid or frothy. The left base cleared up considerably, but the right middle lobe became implicated. During the night from the 11th to the 12th there was not much sleep, and his Royal Highness's condition in the morning was not very satisfactory. The physical signs gave evidence of further clearing up of the lungs in the course of the day; nourishment was taken well, and the pulse continued good, but in the evening the patient became more excited, and during the night very delirious. The delirium continued throughout the day, and this constituted the dominant feature of the illness. The consolidation of the lungs had almost entirely disappeared on Wednesday, but fine crepitation was present. Marked improvement took place in the early part of the night of the 13th; the delirium was less violent and less continuous, with intervals of sleep, but about 2 A.M. on the 14th collapse suddenly supervened, with unconsciousness and absence of conjunctival reflex. A rally from this condition took place, but his Royal Highness gradually sank and died about 9.10 A.M.

The details of the illness are thus in agreement with the now familar fact that when pneumonia supervenes upon influenza it is mostly insidious in its onset, and very serious in its course. To some extent this is doubtless due to the effect which the influenza virus has in depressing the vital powers, and it sufficiently accounts for the exceptional fatality of pneumonia after influenza. It will be observed that the illness did not begin with any definite rigor, and that the signs of consolidation only appeared on the 9th inst. Thus it is somewhat difficult to determine the precise duration of the pulmonary affection; but it is probable that the pneumonic fever was approaching the crisis—the period at which death mostly occurs. The pneumonic consolidation, which was limited at first to the lower lobe of the left lung, involved on the 10th also the base of the right lung. Moreover, it began to clear up from the former organ whilst it was extending in the latter. The rapidity with which this resolution was taking place is one of the remarkable features of the attack; whilst the character of the expectoration, the degree of fever, and the pulse rate did not seem to indicate any special gravity. But there appears to have been a serious change for the worse during the night of the 12th, which was announced in the somewhat alarming bulletin issued the following morning. His Royal Highness appears to have become very delirious, and these cerebral symptoms persisted throughout the 13th, constituting the chief feature of the case, for the signs of pulmonary inflammation were subsiding, and the fever was abating. Moreover, his pulse remained fairly good, and in the evening of the 13th a rally took place which must have considerably raised the hopes of his medical attendants as to his recovery, seeing that the period of crisis must then have been nearly reached. That rally, unhappily, proved to be delusive, and a rapid failure of the vital powers set in early in the morning of the 14th.

PERHAPS it is not unnatural that the public should feel a little impatience of the influenza, and of the medical profession for not more effectively curtailing its prevalence and the mischief which it works. Under the influence of medicine in its sanitary and curative work epidemics have been greatly restrained as respects both their area and their mortality. We have almost ceased to dread cholera since Dr. SNOW, Mr. JOHN NETTEN RADCLIFFE, and others showed how its diffusion is accomplished, and therefore how it can be avoided. Typhus fever is a curiosity in London, and even in Dublin it is becoming a rarity. No one need die of small-pox; indeed, no one need have it unless he likes—that is to say, he can be absolutely protected by vaccination, once repeated. It is so scarce for the moment that foolish people think it has been permanently altered or weakened by fresh air or good drainage, and are putting on an air of contempt for vaccination which will not long survive a veritable resuscitation of this very serious and horrible disease. But, lest we should be unduly exalted, an epidemic of influenza reappears for the third time; and the criticism of some of the public and of the newspapers is uncomplimentary. The alleged discovery of a bacillus is treated with playful incredulity or something worse, and the general action of the profession in regard to the disease is abused. We venture to say that this view of the subject is not quite reasonable. The public is asking for what cannot in the nature of things be expected. Here is a disease which on its appearance in 1890 was new to the great body of men now in practice, undergoing a natural process and tending, under good conditions and judicious treatment, to a favourable issue in the majority of cases. The discovery of a bacillus is not yet confirmed; but it is highly probable. It is childish impatience in these circumstances to cry out all at once, "What is the good of such a discovery? What has come of the discovery of the tubercle bacillus? Are we to go once more through the dreary ordeal of the delusion experienced for the cure of tuberculosis by the injection of KOCH'S fluid?" If there be a specific organism at the root of influenza and its efficient cause, surely it is well that we should know it. We must catch our hare before we can cook it. We gain immensely in clearness if we can but establish the fact of such an organism, having the same relation to influenza as the tubercle bacillus has to tuberculosis or the bacillus anthracis to anthrax. We do not hear the same petulant complaint against typhoid fever or small-pox, because they have to run a definite course, generally much longer and much graver than is the case with influenza. The medical profession is not ridiculed and abused because it cannot stop abruptly the course of these diseases. It is recognised to be doing a great service to mankind in studying the chief risks of such diseases, the best way of avoiding such risks and of conducting the patients safely through them. The profession is doing the same with reference to influenza, and in many ways mitigating the suffering which it causes and limiting the mischief which it is apt to do. The rapid diffusion of the disease as compared with that of other contagions is a fact which requires further elucidation. But that is largely in the hands of the public, who have not yet learned to regard cases of it with that dread with which they regard small-pox or scarlet fever, and who refuse to take the same precautions which they adopt in regard to these diseases. The want of a wholesome fear of the disease does harm in two ways. It leads those who have the premonitory symptoms to disregard them, and to use insufficient means of saving and protecting themselves; and secondly, to carelessness with regard to risks of infection. Early application for medical advice and the diligent observance of such advice would save patients from many complications of the disease which tend to make it long or grave, and would have the further effect of limiting the spread of the infection—for there can be no longer any doubt of the infectious nature of the disease. It is not our object here to enlarge on the treatment of influenza or on the undoubted value of many measures and remedies at different stages of the disease, but rather to assure the public through the profession that medical practitioners are deeply engaged in the systematic study of the malady in all its personal and public bearings.

THE reports which have just been issued as to the prevalence of diphtheria and allied sickness at Wellington College hardly raise any points that have not long been before the public. In January, 1884, precisely the same subject was under discussion in the pages of THE LANCET. During the preceding year 175 cases of throat illness had occurred; 93 were set down as "diphtheritic throats," and 82 as "sore-throats." It was then pointed out that underneath a surface soil of sand there was a bed of clay and an "iron-pan," an iron oxide concretion between the clay and the surface, which seriously affected the natural drainage; mists and fogs prevailed in the valley, whilst "mirk bottom" was supposed to tell the tale of its damp hollow by its characteristic name; and the opinion was expressed that there was ample, apart from certain sewage defects, "to give the diphtheritic character to what would otherwise be a simple sore-throat." And by way of proof, another school near by was referred to where these conditions did not obtain, and it was asserted that for fourteen years no case of diphtheritic throat and no single case of acute lung disease had occurred. These opinions were set out by Mr. BARFORD, medical officer to the College, and they were the result of twenty-two years of observation. Much controversy arose at the time, but even those who denied that the physical circumstances, combined with certain sanitary defects, had concern in the production of the throat mischief and in the special characters which it tended to assume were agreed that alterations were needed in the direction of doing away with the circumstances which had been complained of and certain works were in consequence carried out.

Once again reports relating to Wellington College are before the public; again they relate to diphtheria and to throat disease; again the general sanitary circumstances of the College and of its surroundings are in question; and again Mr. BARFORD calls attention to conditions similar to those prevailing in 1884. His communication will be found elsewhere. During the concluding term of last year no fewer than 244 boys were received into the sanatorium before the school was prematurely closed, by the advice of Sir ANDREW CLARK, on Dec. 2nd. The prevailing disease is believed to have been

Digitized by Google

influenza in the first instance; but later on, according to Dr. BRISTOWE'S report, Mr. ARMSTRONG, the medical officer to the College, said that either some aggravation of local conditions must be affecting the health of the boys injuriously or some new specific malady had been introduced. Dr. BRISTOWE is not a believer in the progressive development of the property of infectiveness as exemplified by diphtheria, and it will be immaterial for our present purposes to endeavour to explain precisely how the change came about which suddenly caused so much alarm. It is sufficient that a change did come, that febrile symptoms, inflamed throat, and swollen glands in the neck, with swelling or ulceration of the fauces, were followed by cases that were regarded "as malignant or phagedænic ulceration of the throat," and that these latter cases at least were "true diphtheria." Indeed, Dr. BRISTOWE goes further. He has no reasonable doubt that most, if not all, of the cases which, from the similarity and gravity of their symptoms, had caused alarm, were also cases of diphtheria.

But what were the conditions with which this occurrence was associated? Here we seem carried back again to 1884. Dr. BRISTOWE, speaking of the condition of the soil, says that from its peculiar conformation and character there is no doubt but that it tends to become saturated with water and to remain sodden. Here we have a prominent condition with which such recurrences of throat illness and diphtheria are now known to have some intimate relation; and the condition is one which tends to be aggravated by every wet autumnal season of the character of the last three or four months of last year. "It constitutes," says Dr. BRISTOWE, "a grave sanitary defect.' And it is the more grave because it is one of the principal defects that were pointed out in 1884, and which some were at pains to deny. But unfortunately this is not the only defect; mere rainfall is not the cause of diphtheria. "The drainage and other sanitary appliances of the College estate" turn out "to be exceedingly defective," and what with the reconstruction of drains and the deepening of dykes to carry away subsoil water, Mr. ROGERS FIELD, who has the engineering works committed to him, cannot undertake to authorise the College to be reopened until Easter next, and measures are under consideration for tiding over the intervening period.

We are thus face to face with the fact that diphtheria and an allied throat disease have again been prevalent at Wellington College; that the essential conditions which were found to be faulty when the same disease prevailed eight years ago—namely, dampness of site, with its fogs and soil emanations, together with defective drainage arrangements—still prevail on the estate; and that much that was written on the subject in 1884 still applies in the present day. Under these circumstances, it matters very little by what stages, if any, the disease passed from a comparatively innocent to the "malignant" form. Influenza may possibly have been associated with symptoms which, aided by prevailing moisture and faulty sanitation, led to a special condition of fauces which fitted them to receive the diphtheria infection; for, quite apart from the influenza, it may be that one or more of the defective sanitary circumstances referred to in the reports may themselves have induced that "simple follicular tonsillitis" which so commonly precedes recognised diphtheria, and which forms a soil in which the diphtheria organism seems to have a special faculty for developing. However the conditions arose, they present nothing peculiar. The Wellington College outbreak takes its place as one of many very similar ones; and unless the conditions to which prominence is once more given can be effectually removed, it is highly probable that diphtheria will before very long be again heard of in the locality.

Had it not been for Sir ANDREW CLARK'S wise decision to close the school, the mischief might have been much more serious. The disease had apparently just reached that stage when, judging from other outbreaks, it could so easily have been transformed by school aggregations and unhealthy surroundings into a very serious and very fatal diffusion, and it is highly probable that the sudden school closure did much to prevent this taking place. We trust we are right in inferring that the College officials do now seem alive to the real need of doing away with all the faulty conditions that have been prevailing for so many years, and we would again urge that it would be more satisfactory to all concerned to have the College inspected and reported on by some perfectly independent authorities efore the structural works that have been decided on are completed.

AMONGST the many services rendered by thermometry to clinical medicine must be reckoned the discovery of febrile states in certain affections which were previously regarded as running an apyrexial course; and just as systematic observations on the temperature have furnished us with abundant information concerning the type of pyrexia that characterises each one of the specific fevers, so it may eventually prove that certain special types of fever are associated with diseases that run more or less a chronic course. The last contribution made by the late Dr. MURCHISON to clinical medicine, of which he was so ardent and sagacious a follower, was to illustrate from his wide experience the conditions under which intermittent or paroxysmal fever is met with. The clinical lecture in which he adduced these facts was published in these columns just after his death,[1] and in it he dealt, among other affections, with the characteristic pyrexia of lymphadenoma. Since then there have not been wanting many records of cases of malignant disease—mostly of the class of sarcoma—in which irregular pyrexia, often to a very marked degree, has been a notable feature of their clinical course. Indeed, it may be accepted as a clinical fact that the more malignant and diffused forms of sarcoma—those which have been designated by the general term "sarcomatosis"—are invariably accompanied by pyrexia. In 1887 W. EBSTEIN published[2] details of a very remarkable and apparently unique case, which he termed "chronic relapsing fever." It was characterised by alternating periods of high fever and apyrexia, lasting for months; and when, exhausted by increasing weakness, the patient eventually succumbed, the underlying condition was found to be one of malignant lymphosarcoma. Similar types of fever were subsequently recorded by other writers; some in HODGKIN'S disease, as in the examples cited by

MURCHISON, some in internal sarcoma, independent of the lymphatic system.

The latest contribution to this subject—which has given rise to the above remarks, and has also impressed us with the desire that a careful collection and study of cases of this class should be undertaken—is by C. PURITZ, who records a case observed in the clinic of Dr. TSCHUDNOWSKY at St. Petersburg.[3] The patient was a young man twenty-two years of age, who in the autumn of 1889 began to suffer from increasing weakness, dyspnœa, and enlargement of the abdomen. Examination showed the presence of some nodular masses in the abdomen, contiguous to the liver, but it could not be determined whether they were actually connected with that organ—some enlargement of the spleen, and of the axillary and cervical glands. There was also marked anæmia. Four years previously he had acquired a sore on the penis, but this had not been followed by any syphilitic signs, and it may at once be said that the supposition that the conditions were due to syphilitic infection was negatived by the failure of antisyphilitic treatment to modify the cause of his illness. In February, 1890, he began to be febrile, and during the next six months he had several attacks of fever, uninfluenced by quinine, with intervals of freedom from pyrexia. It was in August that he came to the St. Petersburg clinic, and the case was carefully observed to its close in November. It was throughout marked by a high degree of fever of an irregularly remittent and intermittent type wholly uncontrolled by antipyretic remedies, arsenic and other drugs. The masses in the abdomen were thought to be connected with mesenteric and retroperitoneal glands, and the diagnosis of lymphosarcoma was made. The anæmia and weakness increased, and death was preceded by peritonitis. At the post-mortem examination the liver was found to be enormously enlarged, reaching to the pelvis, and the seat of numerous soft whitish masses of new growth, some of which had broken down, whilst the lymphatic glands in the abdomen were unaffected. The spleen was enlarged, as also were the cervical and axillary glands, which had been noticed during life. Such a case must be placed in the category to which EBSTEIN drew attention, although the "relapsing" type of the fever, from which the patient had undoubtedly suffered in the earlier part of his illness, was not maintained to the close. But the category must be enlarged, far beyond the limits conceived of by EBSTEIN, to include a great variety of cases of so-called malignant disease associated with pyrexia. Of course all cases complicated with inflammatory or suppurating processes must be excluded, and yet we doubt not the class of febrile sarcomatosis will remain very considerable. Nor must the association of irregular pyrexia with neoplastic formations be confined to the class of lympho-sarcomata alone. This class, which, on the one hand, comes closely into relation with simple lymphatic hyperplasms, and with HODGKIN'S disease (or "pseudo-leukæmic," as it is termed in Germany), passes, on the other, into what may be regarded as true sarcoma of the lymphatic glands, and, as we see in PURITZ'S case, sarcoma of other internal viscera. It becomes a question for the pathologist to determine how far he is justified in making a distinction on histological grounds between affections which clinically seem to be so closely linked.

This brings us to the interesting speculation as to the possible dependence of "sarcomatosis" upon the growth of infective micro-organisms. It may be straining analogies too much to in any way ally this form of neoplasm with the granulomata that are caused by the microbes of tubercle and syphilis. But there is a growing feeling that malignant growths (so called) are very analogous to infective diseases generally, and that time may eventually reveal their dependence upon parasitic microbes. That these microbes belong to the bacterial class seems improbable, in view of the negative results attending all attempts at the cultivation of such organisms from cancerous formations. But—and the curious association of psorosperms with some forms of epithelial cancer suggests it—it is by no means improbable that organisms of a protozoal kind have to do with the initiation of these malignant formations. This hint is thrown out by PURITZ, who says that sections of the growth from his case exhibited some granules and masses in the protoplasm of some of the cells, which stained very deeply with methyl blue and might be of extrinsic origin. This, however, is a pathological problem which remains for solution, and until methods be discovered for the isolation and cultivation of protozoic organisms analogous to those introduced by KOCH for protophytic microbes, which have yielded such marvellous results, it is difficult to see how the question can be determined. Meanwhile the careful clinical record of such cases, and in particular the observation of all those features in which they resemble infective disease, is likely to be of much service. And, in respect to diagnosis, the occurrence of pyrexia of the type mentioned is something to be borne in mind as characteristic of sarcomatous disease of the internal organs.

[3] Virchow's Archiv, Bd. 126, No. 2.

IT will be seen from an article in another page that the wave of reform in medical education, so far as its practical teaching and results are concerned, has at length reached the Scottish capital. In Edinburgh, in spite of many efforts to restore the balance, during the past ten years, theoretical teaching still largely takes the place of practical work, from even the natural history studies in the first examination to the final requirements in medicine, surgery, and midwifery, for the degree of M.B. and C.M. This defect is largely due, not only to the excessive number of students who have in recent years flocked to the University of Edinburgh either for the purpose of obtaining a degree instead of a diploma or because of the deserved renown of its professoriate, but also because Edinburgh, like Oxford and Cambridge, not being a large manufacturing centre, and not having special means like London for attracting a large roving population, has never been able to furnish an adequate anatomical supply or a sufficiency of clinical cases for the due practical education of its students. This is an old story, and the confirmation of it is strikingly shown in the debates on Practical Midwifery in the General Medical Council. It was there plainly stated that Scotch medical students could not attend the number of cases of midwifery which were judged to be adequate because of the impossibility of finding a sufficient number of cases in

Digitized by Google

proportion to the number of students. It is satisfactory, therefore, to notice that an association, mainly of younger lecturers and teachers, has been formed to increase the practical element in the teaching of the Edinburgh school. With large classes and few assistants, and these relatively very badly paid, it is clear that all personal supervision and instruction are impossible, and it is especially in these respects that the London medical schools have lately been making such rapid strides. Tutorial teaching to small classes is now in nearly every subject superadded to, or even has largely displaced, the more formal lecture. The number of lectures is being reduced to a minimum, and the amount of practical work duly increased, and it will become even more extensive under the five years' curriculum which is now introduced. It is only in accord with the spirit of the modern method of education that practical work in every practical subject—and there is nothing but what is practical in medical art and science—should displace mere theoretical orations. We are therefore all the more pleased to find that the younger members of the University see the necessity of such a reform, and are desirous of initiating it themselves rather than leaving it to be enforced from without. Education and examination can both be improved at Edinburgh by a more liberal introduction of the practical element. The days of professorial teaching to huge classes without knowledge of, or attention to, the wants and ambitions of the individual student are doomed, and the sooner the necessary rearrangements are made so as to secure the instruction of the individual unit the more secure and lasting will be the reputation of the great Edinburgh medical school.

Annotations.

"Ne quid nimis.'

OLD AGE, DISEASE, AND COLD.

IT is only consistent with analogy in natural law that the period of old age should be known as a time of failing vital power. The fact, indeed, may not be accentuated or localised by any striking evidence of deficiency. In many cases the course of change is, like that of the ebbing tide, gradual, observable only by general indications and by comparison with past conditions. The body becomes weaker, less active, its tissues wearing out, but still remaining fairly healthy, preserving well the natural interdependence of different organs, and maintained by a slow but sufficient process of repair and even of development. In aged women more particularly do we note this orderly transitional alteration. In aged men there is, partly from habit of life and partly also, it would seem, as a mere constitutional and sexual characteristic, a tendency to greater organic variation, to degenerative changes in special organs, in the heart, arteries, or urinary organs for example. Some of these changes, indeed, must be regarded as in their way conservative. The flagging heart has a proportionate relation to bloodvessels hardened by senile atheroma. There is greater safety in the double abnormality than if the central pump drove its fluid contents with unabated force through channels which might at any time give way under the pressure. Cerebral deficiency, in like manner, if indicative in itself of progressive nervous degeneration, is from this very circumstance protective against the costly wear of tissue caused by worry. There is another aspect of the case, however, and we cannot doubt that impairment of vitality has much to do with the known readiness of the aged framework to give way under the strain of sudden exposure or of acute illness. We should duly take account of this before we describe as extraordinary or irregular even such marked mortality among the aged as that which has been associated with the recent severe weather. The condition of sluggish and enfeebled life to which we have referred possesses no such power of rapid reaction as is needful to withstand a frost of continuous duration, accompanied in many places by an epidemic of influenza. Death under such conditions is in fact an almost natural consequence In a more primitive era it would have wrought out practically unchecked its part in the physical order, and would have illustrated far more exactly the force of that law which determines the survival of the fittest. Where it has not so wrought we must attribute the result, as a rule, not to ordinary or individual vitality, but rather to the preservative arrangements of civilised intelligence, which provide for suitable food, warmth, and the timely care of apparently trifling signs of illness.

OATH ADMINISTRATION.

UNDER the heading "Kissing the Book," a northern contemporary recently dealt at length with the present mode of oath administration in English courts of law. The subject has been so often alluded to in the pages of THE LANCET that it is only necessary to repeat in brief what has already appeared. Members of the medical profession are more frequently called upon as witnesses than clergymen, members of the bar, solicitors, or indeed members of any other profession. Some have complained of the necessity of having to apply to their lips a book which has been handled and kissed by so many previous witnesses as to become an unclean thing. Others minimise the evil by kissing the open page. A third class conclude that what cannot be cured must be endured, and so submit meekly to what is really not such a trifle as may appear at first sight. The same remark applies to jurors, interpreters, and others. The only persons who are spared the infliction are Quakers and Separatists, and unbelievers, who, however, form but a small proportion of the whole number of jurors or witnesses. It is to be hoped that those with whom rests the responsibility of the continuance of the objectionable practice are not waiting for absolute proof of infection being conveyed by this means—a contingency by no means remote. The loving cup which is handed round at the Lord Mayor's and other banquets may be accepted or refused, but the book must be kissed by the witness, and it is the duty of the person administering the oath to see that this is duly done. It has been suggested that witnesses, especially those whose appearance in the box is frequent, should have their own books, which, as a glance would verify the fact that it was a copy of the Gospels or of the Pentateuch, seems reasonable enough. Another suggestion, however, is that kissing the book should be dispensed with altogether, the form of adjuration being the holding up of the right hand. It is very remarkable that while the kissing of the book has held its own with such persistency in England, Wales, and Ireland, the Scotch have with equal persistency maintained their mode of oath administration, which is by the uplifted right hand, the necessity for handling and kissing a dirty greasy book being thus altogether dispensed with. The superiority of the Scotch mode of adjuration is in this respect manifest. But this is not all. Those who have to frequent courts of law must have been painfully impressed by the total absence of solemnity or reverence too often shown by the person who administers the oath. To the younger members of the medical profession the proceeding savours of a farce, and familiarity does not improve this feeling, but literally and truly breeds contempt.

Digitized by Google

Here, again, the Scotch method is superior. The presiding officer of the court, whether judge or sheriff, rises and holds up his right hand; the witness does the same. The judge repeats the words of the oath, which, it may be added, are simpler but more solemn than the English form, the witness repeating them after the judge. Those who have seen witnesses sworn in both countries unhesitatingly pronounce in favour of that used in Scotland. It is not only more cleanly, but also more solemn and impressive. There will no doubt be difficulties to overcome in the face of established usage; but it is, to say the least, anomalous that two such totally different modes of adjuration should prevail in the same kingdom. Why should there not be some approach to uniformity, that mode being adopted which is in all respects preferable? Judges have complained of the English form as not being simple enough for witnesses of tender age. This cannot be urged against the Scotch form, which is simplicity itself. More recently the oath has been administered by the judge's marshal instead of the court crier, a proceeding suggestive of a gradual approach to the presiding judge, and it is to be hoped to a more radical change. In these pages the matter has been dealt with in the aspect in which it would occur to medical minds. Under no other circumstances are men and women called upon to handle and kiss anything in common. This, however, is only part of the question, the other part of which we have no wish to ignore. On the contrary, it is of the greatest importance that members of the medical profession should when they become witnesses be duly impressed with the solemnity of taking an oath, and have no reason (as they have at present) to regard it with contempt, or even with disgust. A short Act of Parliament, substituting the uplifted right hand for kissing the book and the repetition of the form of words by the witness, is all that is required. It would have much support, and probably little or no opposition. We commend the suggestion to members of Parliament.

INFLUENZA AND LONGEVITY.

WHENEVER a period of low temperature or of fog, or of both in combination, unfavourably affects our rate of mortality, the death-rate of the aged and of elderly persons shows a far higher rate of increase than the death-rate of the young or middle-aged, or even of infants. The veriest tyro of mortality statistics would recognise this as the natural result of the meteorological conditions above referred to. It may be noted, however, that as often as these conditions prevail, and the obituary notices in *The Times*, for instance, consequently show an unduly excessive proportion of deaths of elderly persons, some industrious paragraphist is sure to compile a statistical return showing the number of old people whose deaths have been advertised out of a given number of death notices announced during a given week. These figures are harmless enough in themselves, and useless enough, since no figures are ever given showing what are the normal proportions of the ages of the well-to-do classes whose deaths are so announced. The figures are, however, absolutely mischievous when the paragraphist or correspondent is allowed to draw inferences to the effect that this excessive and exceptional mortality among the aged affords evidence of increasing longevity. It is, however, a fact that during the past fortnight more correspondents than one in our lay contemporaries have referred to the fatal effect of influenza among the aged, judged by the obituary notices in *The Times*, as evidence of increased longevity. It is undoubtedly true that the proportion of deaths of elderly persons under the combined influence of low temperature, fog, and influenza has been abnormally high in recent weeks; but it is impossible to recognise any reasonable grounds on which this influenza mortality can afford evidence of increased longevity. Against such a misuse of statistics we feel bound to record our emphatic protest.

THE LATE CARDINAL MANNING.

UP till recently his Eminence Cardinal Manning, at the age of eighty-four, was in the enjoyment of his usual health and engaged actively in the discharge of the multiform duties belonging to his position. A few days ago he took cold, and on the 11th inst. Mr. Tegart was called in. On seeing the condition of the patient he at once recognised the gravity of the case, and Sir Andrew Clark was asked to see the venerable Cardinal. Dr. Gasquet, who was related to Dr. Manning by marriage, and was his usual attendant, had seen him a week previously, and advised that his Eminence should take to his bed. He suffered a good deal from cough, and on Monday, the 11th, symptoms of bronchitis supervened, accompanied by inability to take food and great prostration of strength. Although the Cardinal was always sparing in his diet and never took wine or stimulants of any kind, he nevertheless had up to this point relished his food. Now, however, he exhibited the greatest repugnance to it. Evidence of slight congestion first of the left lung and afterwards of the right appeared on Tuesday, the 12th, and on Wednesday morning there were further evidences of prostration of strength, with an irregularity of the pulse and increased difficulty of breathing, which continued to increase during the day, and in the evening of Wednesday his failure of strength was seriously marked, and medicine failed to promote the expectoration of the secretion which was filling the bronchial tubes. During the night he was quiet, but gradually got weaker and weaker, and he died at 8 o'clock on Thursday morning. Sir Andrew Clark found the bases of both lungs congested and the heart showed signs of failure by some intermission and irregularity of the pulse. Always ascetic, it was difficult to persuade the Cardinal to take the requisite amount of food and stimulants necessary to his sustenance in the circumstances. The progress of failure was so rapid that it may fairly be doubted whether either food or remedies would have had much good effect. On Wednesday evening the heart became much weaker, and it was obvious that his end was at hand. Nevertheless his intellect remained quite clear. He transacted a considerable amount of business, and enjoyed afterwards a placid sleep On the 14th inst., at 8 o'clock, the heart having failed, his Eminence, as already stated, died, free from suffering and conscious to the last.

EFFECTS OF TIGHT-LACING.

IN the number of the *Edinburgh Medical Journal* for the current month Dr. Johnson Symington describes the conditions which were found in the body of a woman of fifty in whom the effects of tight lacing were very obvious. As regards the chest, he found that down to the level of the fourth costal cartilages the sternum was convex and prominent and the intercostal spaces large. This part of the chest was flattened from side to side, the antero-posterior diameter opposite the third costal cartilage being 8 in.; while the transverse was only 7½ in. The lower part of the thoracic wall was greatly contracted, the lower costal cartilages being pushed inwards, so that the right and left seventh cartilages were in close contact with each other from their attachment to the sternum downwards for 2½ in. There they touched the tips of the eighth costal cartilages which not only approximated in the middle line, but slightly overlapped each other. At the level of the fourth costal cartilages the circumference of the chest after removal of the integuments was 27 in., while opposite the lowest part of

Digitized by Google

the eighth costal cartilage it was only 17 in., and with slight pressure this could be reduced to 16 in. The liver was less altered than is usually described. The lower part of the right lobe was pushed inwards, and the right and anterior surfaces showed a distinct depression running outwards and upwards for 2½ in. In this the tenth rib was lodged. Almost the whole of the gall-bladder projected beyond the lower edge of the liver. When the stomach was filled with air it showed a distinct constriction about the middle of its vertical portion, and the pylorus was not overlapped, as it usually is, by the liver. Both large and small intestines were distinctly lower than normal, but the kidneys and spleen had undergone no material change in position or form. The careful study of such a case from the anatomist's point of view is of the utmost importance, and the changes, both in position and form, evident in important organs in the case just described will, we hope, emphasise the evils of an absurd and silly custom.

CURIOUS NERVOUS DISEASE IN MEMBERS OF THE SAME FAMILY.

IN the last number of the *Neurologisches Centralblatt* there is an abstract of a paper by Bernhardt in Virchow's *Archiv* describing a curious and interesting condition which he found in several members of the same family. The parents were apparently healthy. They had in all eight children—six boys and two girls. One of the girls died at an early age, and suffered in a similar way to that about to be described as affecting two brothers. The second sister was neurotic, but otherwise free from signs of organic disease. Her children and grandchild were healthy. Two of the six brothers died before they were thirty, and did not suffer from the affection. The only child of one who died is healthy; the two children of the other brother who died are imbeciles. A third brother also died, but after attaining a greater age, and he apparently suffered in the same way as the three surviving brothers. These developed about the thirtieth year a very slowly progressive paralysis limited to the lower limbs, and consisting in muscular rigidity with increased reflexes, but without any sensory or trophic disturbances. The functions of bladder and bowel were retained, and intelligence was not interfered with. In one of the three in whom symptoms have been present for over ten years there have been added more lately symptoms indicating that the process has spread to the medulla and pons, and perhaps also has invaded the cerebrum itself. These symptoms are disturbance of articulation, paresis of isolated eye muscles, and nystagmus. The symptoms, it will be seen, resemble in some particulars those of disseminated sclerosis, but in the mode in which it attacks several members of a family it bears a close analogy to the ataxy of Friederich.

THE GREENING OF PEAS WITH SULPHATE OF COPPER.

THOSE who have maintained that peas coloured with sulphate of copper are injurious to health will hear with disappointment the decision given by Sheriff Birnie at the conclusion of the recent appeal suit in Glasgow. The case has occupied the attention of the court over an extended period, and much evidence of a conflicting kind has been heard. The experts engaged for the prosecution held sulphate of copper to be a cumulative poison, and they further argued that the albuminate formed by the copper salt with the legumen of the pea was soluble in the digestive juices. For the defence, on the other hand, statements were made to the effect that several tins of the brand of peas in question were used in certain families without any ill effects resulting, and experiments were cited which went to show that the compound of legumen of peas with sulphate of copper was practically insoluble, and did not enter the system, and was therefore to be considered inert and harmless. The sheriff, in giving judgment, said he expected that in this case he would have had evidence on the two points obviously desiderated—first, of practical injury from eating these peas; and secondly, of the difference between 1·4 and 2·5. (It was stated in the mass of evidence that while 1·4 grains might be innocuous, 2·5 grains were positively poisonous.) He had had none of that, and the facts remained precisely as in the previous case. It had not been proved that these peas had been injurious to health, and he therefore assoilzied the respondent. If it be true, as stated in the evidence for the defence, that the valuable nitrogenous constituent of peas—viz., legumen—combines with the copper, it follows that peas so treated are not rendered any more digestible or nutritious, since it is distinctly affirmed that the copper albuminate formed was practically insoluble, and therefore did not enter the system. In spite of this decision, analysts would do well, as hitherto, to report the fact of the presence of copper in any article of food which they may happen to examine. But of course as long as it is accepted by our legal authorities that small quantities of copper are not injurious to health, all attempts to prosecute on this ground must prove abortive. Meantime it would seem desirable that vendors of such coloured articles should be compelled to state with what substance, and to what extent, food materials are coloured. It cannot be denied that even small quantities of copper in food, though comparatively harmless to healthy adults, may not improbably give rise to unpleasant consequences in an invalid or child.

THE DEATH OF THE KHEDIVE OF EGYPT.

THE account given by Dr. Salem Pasha of the fatal illness of the late Khedive of Egypt, and published in the *Daily Telegraph* of the 13th inst., leaves unfortunately but little doubt that his death was accelerated by mistaken treatment. Dr. Salem Pasha was called to the Khedive on Jan. 1st, and found him suffering from influenza and bronchitis. For a few days he improved, but on the 5th there was a relapse of fever and increased catarrh, with much weakness. In the early morning of the 6th Dr. Salem Pasha was hastily summoned to the patient, and found him unconscious, suffering from great dyspnœa, and a temperature of 104° F. He learnt that the Khedive's aide-de-camp had at 9 P.M. administered a hypodermic injection of morphia, and the European physicians who had been summoned were unable to arrive until shortly after Dr. Salem Pasha. Death was attributed to uræmia, but Dr. Salem Pasha asserts that he was not made aware of the fact that his Highness had renal disease. His report is certainly not very clear; but we fear that if nephritis really existed, the injection must have materially aided in bringing about the fatal result.

THE EXTRACTION OF TEETH FOR DENTAL IRREGULARITIES.

MR. ALEX. KIRBY'S paper on Extraction considered as a Means of Correcting Dental Irregularity, read before the Eastern Counties Branch of the British Dental Association, deals with a subject of both importance and interest. As to the causes of irregularity, he says that the first thing which suggests itself to the mind is the crowding of more teeth into the dental arch than it can properly contain; and there can be little doubt that the maxillæ of the present day are relatively smaller, when compared with the size of the teeth, than was the case in the well-developed heads during the early history of the human race, and that the teeth themselves have undergone during the same period far less degeneration in size than have the maxillæ. Crowding being the great

Digitized by Google

evil to be combated, it frequently becomes a question of removing a tooth or teeth to make room for the remainder; and if a regulation can be brought about by the forceps alone, it is the best practice to employ. If the deformity can be removed by the extraction of one tooth only, such as a supernumerary, decision as to procedure is simple. A lateral or even a canine may sometimes be removed and give an immediately good result, but great care ought to be exercised and judgment brought to bear before a canine is removed, as it is a tooth little liable to decay. Of course, where practicable a decayed tooth should be removed in preference to a sound one. In the majority of cases Mr. Kirby is of opinion that the six-year-old molars should be sacrificed rather than the bicuspids, because this treatment gives more room; no gaps are left in the mouth, since if the whole space is greater than that required by the irregular teeth the second molar will come forward, and approximate to the bicuspid; and, further, the six-year-old molar has a bad history, according to statistics it being far more prone to decay than any other tooth. He thought that, although no hard-and-fast rule could be laid down, the best time for this operation was between nine and eleven years of age; then a considerable interval should be allowed to elapse before any mechanical treatment is adopted, and in many instances so much improvement will follow as to render it unnecessary to do anything further.

MICROBES IN THE SOIL.

ALMOST daily fresh evidence is accumulating as to our dependence upon microbial action for the supply of vegetable food and for the conversion of refuse matter into nutriment for the various plants which supply us with vegetable food. Only a fortnight ago we gave insertion to a paper by Dr. F. B. Wells and Dr. Poore which showed in a conclusive way the extraordinary power which common earth has of retaining the organic and inorganic constituents of urine and converting them by a process of nitrification into food available for plants. Further papers bearing upon the same subject will be found in the current number of the Journal of the Royal Agricultural Society, a journal which, in the hands of its present editor, Mr. Ernest Clarke, has made rapid strides, and bids fair to be of the greatest value in disseminating a scientific spirit among our agriculturists. The paper by Dr. Munro on the nitrifying ferments of the soil is a most excellent summary of the subject, which should be read by all who are interested in the matters discussed. It shows, what is being shown almost daily, how strictly scientific have been some of the processes which have been familiar for ages, although the explanation of the process may not have been apparent. "To the natural process of nitrification as it occurs in the nitre-producing villages of India, Europe has been, and still is, largely indebted for a supply of nitrate of potash wherewith to make gunpowder. The heaps of nitre earth found near the sites of former habitations consist of house refuse mixed with porous soil, ashes from the fires, urine, &c. After long-continued exposure to Indian warmth lixiviation of this nitre earth with water furnishes a solution from which saltpetre is extracted by evaporation and crystallisation. In 1877, when France could not import saltpetre, the Government caused to be printed 'Instructions for the Establishment of Nitre Heaps,' which Boussingault makes the subject of one of his essays. ..... Heaps of soil, mixed with ashes and animal refuse arranged in layers separated by loose straw, kept under cover freely exposed to air, and watered as often as possible with urine, turned and removed once or twice if practicable, furnished in the course of some months a notable supply of nitre. If treated after the manner prescribed we learn that about 450 tons of material would in two years furnish about four tons and a half of crude saltpetre." The other paper to which we have alluded is also one of great importance, and shows again how agricultural practice has been right, although the explanation was not forthcoming. The custom to which we allude is that of sowing leguminous plants for the purpose of enriching the soil, and following the leguminous crop with one of the cereals. This custom, practised by the Romans 2000 years ago, is one which the most recent advances in bacteriology show to be correct. The paper on the Sources of Nitrogen of our Leguminous Crops, by Sir John Lawes and Dr. Gilbert, not only gives an excellent summary of what has been done by previous workers, but also affords details of their own most important experiments. It has long been known that the addition of nitrogenous manures had very little effect upon the growth of the leguminosæ, and it has now, we think, been conclusively shown that many at least of the papilionaceous leguminosæ (peas, beans, lupins, &c.) derive their nitrogen from the air circulating in the earth around their roots, and that the appropriation of this nitrogen is due to nodules growing upon the roots, which nodules are in a sense parasitic and are largely composed of bacilli. The experiment of growing leguminosæ in sterilised soil, and of showing that no vigorous growth takes place until such soil has been "seeded" with the washings of a leguminous soil containing the necessary microbes, has been repeated by Sir John Lawes and Dr. Gilbert with complete success. This dependence of plant growth upon the existence of parasitic bacillary nodules upon the roots is a fact of great interest, and indications are not wanting that this may be only the first demonstration of such dependence, and that further investigations will show that microbes minister to the nutrition of other plants in more direct ways than hitherto we have had any idea of. This paper by Sir John Lawes and Dr. Gilbert is one of some length, and we have only been able to give the baldest possible indication of its scope and importance.

CHINA MEDICAL REPORTS.

WE would call the attention of medical officers and such of our readers as are now practising, or likely to practise, abroad to the Medical Reports from China, published half-yearly by order of the Inspector-General of Customs. These reports are furnished by the Customs medical officers, and contain a large amount of useful information, some of which is not elsewhere obtainable. That for the half-year ending March 31st, 1889, for example, is one of a special series of reports. Besides dealing with the health of the communities—European and native—in the districts of Tientsin, Canton, Wuhu, and Shanghai, it contains an excellent summary of observations on enteric fever as it is encountered abroad. Under the head of clinical studies of disease as observed in China this form of fever, of course, comes under notice, and the contribution to its study embodies the consideration of a number of interesting points which are deserving of attention on account of their practical nature and the judicious way in which they are generally discussed.

THE RECENT COMPLAINT AGAINST CORONERS' COURTS.

MR. LAWSON TAIT has done good service in directing public attention to two illustrations of the tendency of coroners and their juries to exceed their functions or to forget their duties. There cannot be a more obvious duty for a coroner than to insist that no man shall be condemned in his court without being heard. Yet Mr. Tait shows without any doubt that in the case of Mr. Haynes, on which we commented at the time, the coroner, against

Digitized by Google

his own better sense, allowed the jury to censure a medical man who did not know of the inquest being held, who was, in fact, many miles distant, and who had done all that could be done for the patient. One of our contemporaries seems to think that it is a rare circumstance for a coroner to dispense with medical evidence. But it is no rare occurrence, and coroners and juries, especially where the coroner is not a medical coroner, arrive, without such evidence, but with dangerous facility, at a verdict of the cause of death. In the other case to which Mr. Tait has directed attention the inquiry had reference to the death of a young woman who some time previously had given birth to an illegitimate child. There was nothing in the medical evidence to connect the death with the birth of the child, yet the coroner thought it his duty to inquire from the sister of the woman into the delicate question of the paternity of the child, declaring it to be absolutely wrong that the father should be spared when the poor unfortunate young woman lost her life. It is true that many men escape in such case, and elude the punishment of their meanness and sin, while the woman has all the shame and the hardship to bear; and doubtless any practicable law that would tend to expose such iniquity should be welcomed. But what are we to think of a coroner who could allow his jury, or rather himself, to go into such matters, especially in the absence of the accused person, and to mix up a simple question of the cause of death with the delicate one of the cause of the birth of another person altogether. Such roving excursions bring the coroner's court into disrespect, and convince us more and more of the necessity for medical coroners.

PATIENTS AND THEIR FEES.

THE *St. James's Gazette* of the 8th inst. has a playful article on the subject of "Patients and their Fees, from the Doctor's Point of View," concluding "that if there were no patients' and relatives' whims to consider, and no bills to send in, medicine would be a delightful profession; but it is not." No doubt bills are a nuisance, though a sad necessity; but we shall not admit that they spoil "a delightful profession," and "even the whims of patients and relatives" have their uses. The study of them is often extremely interesting, and affords one of the best clues to the management and treatment of cases.

INFLUENZA A HUNDRED AND SIXTY YEARS AGO.

AN Italian correspondent reminds us of the historic epidemic of influenza in Milan between the years 1730–33, described by the contemporary physicians, Drs. Gagliardi, Bellegatta, and Crivelli. The last named, a Milanese practitioner in advance of his time, found in the air the "chief and efficient cause of the influenza visitation." In 1730 and 1733 the climatic conditions were as nearly as possible the same as those prevalent in the last two epidemics in Italy; that is to say, a mild temperature, the sirocco wind predominant, and much humidity, with fog and rainfall alternating. Dr. Crivelli's description of the symptoms of an influenza patient might (our correspondent says) be transcribed from the phenomena of to-day: "Gravedo and coryza, general languor with indisposition to exertion of any kind, loss of appetite even in presence of the daintiest viands, pain in the sinciput, giddiness, dimness of eyesight, high fever with rigors and *horripilatio* extending over the whole body; cough sometimes moist, sometimes dry enough to induce a choking sensation." These symptoms, not very grave in themselves, says Dr. Crivelli, are apt to reach an acute and even pernicious stage — "the patient finding himself suddenly oppressed with a suffocating catarrh (*un catarro soffocativo*), or, in other cases, with a pleurisy, or a pleuro-pneumonia. One patient falls as by an apoplectic stroke, another complains of intolerable cephalalgia—the old, the phthisical, the asthmatic rarely outriding the storm." It would be difficult to give a truer account of the course and issue of the influenza cases now occurring at this hour in the Alta Italia. Dr. Crivelli further shows himself ahead of his age in his severe condemnation of indiscriminate venesection, stigmatises the abuse of diluents, and rests his system of treatment on vigilantly regulated diet and the support of nature. Of course, he used heroic measures when time was precious—even bloodletting when engorgement of the circulation was a distressing symptom,—and he found great efficacy in the Hippocratic prescription: "Alvus curanda est per clysterem subducentem et frigefacientem." Other less rational measures he also recommends, taken from a pharmacopœia happily superseded. But, according to the lights available at the time, he seems to have been a thoughtful and ingenious clinician, and his treatise has a quite special interest for the student of the history of medicine.

THE DEFECTS OF SCOTCH SANITARY LAW.

SCOTCH sanitarians have certain very obvious grievances, and they have recently taken the opportunity of bringing some of them before the Lord Advocate, who has promised to lay them before the Marquis of Lothian, H.M. Secretary of State for Scotland. One relates to the impossibility of properly getting rid of accumulations of excreta and filth, a well-recognised and a fertile source of preventable disease; and their demand is that districts for cleansing should be made for this purpose in the same way as is done for the purposes of water-supply and drainage. The two latter are largely arranged with a view to local conditions of topographical formation, with which a mere question of cleansing would have little or no concern; and we believe that in this country difficulty has arisen in dividing parishes for mere purposes of scavenging in the same way as has been done where special drainage districts have been formed, the new area being financially and rateably distinct for the particular purpose specified. But the Lord Advocate, whilst hinting at such difficulties, practically admitted that the only alternative was to allow the nuisance to occur, then to seek its abatement, and then let it recur. No one in the present day would for a moment contend that this constituted sanitary administration, and hence the difficulty is one which ought to be faced and dealt with. Another grievance is that, unlike their English colleagues, the Scotch medical officers of health are not periodically provided with the necessary statistical data from registrars of births and deaths as to the births and causes of death, which would enable them properly to compile the statistics required, not only for their own purposes, but for the purposes of the Board of Supervision. This should certainly be attended to, and it would be well if, in any amendment of law as to this, registrars in England could be compelled to give to medical officers of health more details as to births, such as the question of sex, than is now required by the English Registrar-General. Accurate statistics giving details such as these are often not procurable, even by English health officers. Another grievance is that whereas three English permissive Acts were passed in 1889 and 1890—namely, those relating to compulsory notification, the Infectious Diseases Prevention Act, 1890, and the Public Health Amendments Acts, 1890—and whereas the former of these was made applicable to Scotland, the two latter were not extended in the same way. The Scotch sanitarians, whose views were advocated by Dr. Littlejohn, Dr. J. B. Russell, Dr. J. C. McVail, and Dr. Campbell Munro, declare that many of the clauses in the latter Acts had already been adopted in local Acts with

Digitized by Google

the approval of the Board of Supervision; that the advantages of the Act relating to notification cannot be reaped without the further benefit of the other Acts, and yet that Scotland was, without explanation, excluded from their benefits. One thing is certain, and that is that those who know the real sanitary needs of Scotland have now indicated to the Scotch Secretary of State a few simple expedients by which the sanitary administration of their country could be materially benefited, and without which Scotch public health must necessarily suffer to an extent that is no longer permissible in England; and it certainly behoves those who are in authority to see that the comparatively simple, although very important, demands made should be granted with a view to the removal of conditions tending to ensure nuisances and disease and to the prevention of those forms of sickness and death which are now proved to come within the scope of efficient sanitary administration.

DR. COLLIE AND THE ASYLUMS BOARD.

WE are glad to state that, notwithstanding an apparently organised and ungracious opposition, the Metropolitan Asylums Board have recognised the fairness of awarding a pension to Dr. Collie for the eminent services he has rendered to the profession and the public while at the Eastern Hospital and elsewhere in connexion with diseases of an epidemic nature. Dr. Collie has been granted the sum of £210 annually as a pension. It is to be hoped that the good work he has done in organising the methods of combating small-pox and of investigating the nature of virulent epidemic diseases will be only preliminary to further efforts on his part to elucidate some of the obscurity with which they are still surrounded.

THE ANALYSIS OF PEPTONES.

THE compounds obtained in the digestion of meat by acid pepsin, although similar in composition, are by no means identical in chemical properties or nutritive value. Any analytical method therefore which gives a tolerably accurate account of the composition of commercial peptone preparations must prove one of importance and value to the practitioner, seeing that peptones are largely employed as nutrients in cases of enfeebled digestion and in wasting diseases. At the last meeting of the Society of Public Analysts held at Burlington House, Messrs. C. W. Heaton and S. A. Vasey of Charing-cross Hospital contributed an interesting paper on this subject. These chemists have devoted their attention to the methods which have from time to time been proposed, and while they recognise in Denaeyer's method[1] the best that has been devised, and one by which they have been mainly guided, yet they are led to think from their own experimental observations that the process of which the following is an outline is simpler and more satisfactory. A convenient quantity of liquid peptone is gradually dropped into strong alcohol. The precipitate, consisting of albumens, gelatine (coagulable), albumose, and peptone, is dried and weighed. The filtrate, containing meat bases, creatine, &c., and uncoagulable gelatine, is decanted and reserved for further treatment. After weighing the alcoholic precipitate, it is dissolved in water, and the insoluble albumens filtered off and weighed. An aliquot portion of the filtrate, which now contains only albumose, gelatine, and peptone, is next treated with saturated ammonium sulphate solution and the precipitated albumose and gelatine weighed on a tared filter. The adherent sulphate is estimated by means of barium chloride and deducted, together with the filter, from the total weight. Another portion of the filtrate is treated with specially prepared copper hydrate emulsion, which, with albumose, forms an insoluble compound. The precipitate is treated for nitrogen by the Kjeldahl process. Multiplied by the factor 6·33, this gives albumose. The filtrate from the copper emulsion, now free from albumose, is concentrated, and then treated with ammonium sulphate, heated and cooled. By careful manipulation the gelatine which separates may be made to adhere to the sides of the beaker, washed with ice-cold water, and weighed. Adherent sulphate is estimated and deducted as before. The quantity of gelatine and albumose being ascertained, that of peptone may obviously be gained by difference. Part of the alcohol filtrate (*vide supra*) is evaporated to dryness, taken up with water, and treated with ammonium sulphate for the separation of uncoagulable gelatine. Another portion may be evaporated to dryness and weighed, and another taken for the estimation of nitrogen. The following data are furnished by this process: albumens coagulated by alcohol, gelatine (uncoagulable and coagulable), albumose, peptone, and substances soluble in alcohol, such as creatine, urea, &c. Total nitrogen, water, organic matter, and mineral matter are estimated in the usual way. The authors give to Denaeyer the credit of first recognising in peptones a variety of gelatine soluble in alcohol, and they also add that his process was the first to provide for the estimation of gelatine, or glue-peptone. A knowledge of the presence and amount of this body is desirable, inasmuch as it is said not to present the nutritive value of either the albumens or their peptones.

[1] See THE LANCET, May 2nd, 1891.

DEATH OF PROFESSOR VON BRÜCKE.

IN the death of Ernst Wilhelm von Brücke, which took place from influenza at Vienna on Jan. 5th, physiology has lost one of its most illustrious followers. Professor Brücke was born in 1819, and had therefore attained his seventy-third year. He studied medicine at Heidelberg and Berlin, and in 1843 became assistant in the Museum of Comparative Anatomy at the latter University under the direction of Johannes Müller. In 1848 he succeeded Burdach as Extraordinary Professor of Physiology at Königsberg, and the following year became Professor of Physiology at the University of Vienna. There he has remained, steadily working in the sphere of science, and becoming the recipient of many honours. Professor Brücke contributed considerably to physiological literature as well as to anatomy, his works comprising two volumes of lectures on physiology, researches on the blood, on electrotonus, on the function of speech, on colour-vision and other optical questions, as well as anatomical studies of the eye, and, quite recently, a handbook of artistic anatomy.

YELLOW FEVER.

YELLOW FEVER is a disease which prevails in the tropics principally between 25° north latitude and 10° south. It is always found more or less on the Guinea coast of Africa, in Brazil, Mexico, and in the southern part of the United States. Its infectious nature is supposed to be shown by the fact that it overflows these tropical limits every now and again and reaches subtropical regions. It is not known, however, in temperate climates. Certain cities like New Orleans, Rio Janeiro, and Santos are frequently scourged with this disease. Lord Salisbury has received a despatch from the British Consul at Santos depicting the state of affairs prevalent there, and pointing out that yellow fever, together with small-pox, largely prevails. It states that "the former is chiefly caused by the unhealthy state of the harbour, and the monstrous delays experienced in unloading vessels. Nearly two-thirds of the cases attacked end fatally." It is difficult to ascertain the exact etiology of

Digitized by Google

the disease, whether, for instance, it is due to malarial or atmospheric conditions, or to faecal accumulations, and consequently no treatment which is known is able to adequately cope with it. Mr. Edwin Lawrence, in a communication we have received, points out that it is known that at New Orleans so soon as the first frost appears yellow fever disappears, and sea captains know that if they can steam for colder regions the patients on board recover and no fresh cases arise; and he has suggested a mode of treatment by placing the patients, even in tropical countries, in an artificial ice atmosphere on board ships, to place ice in the patients' mouths, and to ice all foods and drinks. The idea seems at least worthy of a trial, especially as it is not difficult in any climate to keep a chamber at freezing-point, or at any temperature below it, and the expense is comparatively small. It is unfortunately the case that the etiology of this fatal disease is as little known now as it was at the time of Columbus, and its effects have been scarcely, if at all, alleviated. It forms one of those unexplored regions of the dark continent of medical science concerning which much investigation is still required by the scientific minds in the profession.

THE FOLKESTONE HEALTH OFFICER.

THE attitude adopted by the majority of the Folkestone Town Council in regard to the appointment of a medical officer of health is not one which is calculated to inspire confidence in the minds of the many visitors who have been in the habit of frequenting that town in quest of health and recreation. The discussion has related to the question of salary, and the dispute has had to do with either a remuneration just sufficient to compensate for a perfunctory performance of the ordinary duties of the office—that is to say, as one member put it, to secure one hour's services for six days in the week,—or, on the other hand, to indicate by a somewhat higher salary that Folkestone desires to attract to the office some skilled practitioner who will really make the health requirements of the place a constant care and study. The majority prefer the former class of appointment, and decline to pay more than "6*s.* or 7*s.* an hour" for one hour's services every week-day. More than once the Local Government Board have had to intervene in connexion with preventable disease in and around Folkestone; and it would certainly conduce to the sanitary interests of the place if it were understood that the Town Council desire for the future to place their town above suspicion as regards its sanitary administration.

THE PHRENIC NERVE.

IN the recent number of *Brain* Dr. John Ferguson of Toronto has a note on the function of this nerve. He had under observation some time ago a patient suffering from progressive muscular atrophy, in whom there was an affection of the diaphragm. The phrenic nerve was examined after the patient's death, and while some fibres were found to be completely degenerated, others were undergoing degeneration, and a third set were quite healthy. He drew the inference that the phrenic nerve was not wholly motor, but in part sensory. To support his hypothesis, he examined the condition in a cat after division of the right phrenic nerve, and three weeks later, on opening the abdomen, the sensibility of the diaphragm was found much impaired. The nerve was completely degenerated. In another experiment the posterior roots of the third, fourth, fifth, and sixth cervical nerves were divided, and subsequent examination of the nerve showed that there was well-marked degeneration of about a third of its fibres. Before the animal was killed it was found to be anæsthetic on the side of its diaphragm corresponding to which the posterior roots had been divided. Dr. Ferguson concludes from these facts that the phrenic is to be regarded as a mixed nerve, and that in inflammations involving the diaphragm or the serous membranes attached to it we may look for sensory disturbances, often of wide distribution. The phrenic being sensory, from irritation of that nerve, pain in the cervical region where it arises is to be looked for, and in this way he accounts for severe pain at the back of the neck and in the shoulder in a patient whom he had under his care suffering from an abscess of the liver which subsequently proved fatal.

HOSPITAL SUNDAY IN LIVERPOOL.

THE second Sunday in the new year has since the year 1871 been observed as Hospital Sunday in Liverpool. Its recurrence this year was therefore invested with unusual importance, Hospital Sunday having thus completed its majority in Liverpool. The day, though cold, was fine and bright, but the state of the streets, frozen and slippery in the extreme, had a marked effect in reducing the number of church and chapel-goers. Still it is gratifying to note that the collections show their usual munificence. At the head of the list is the Sefton Park Presbyterian Church, the minister of which is the Rev. John Watson, one of the Honorary Secretaries of the Hospital Sunday Committee. Here the collection amounted to the excellent total of £666, an increase of £25 over the amount realised last year. Next comes the Renshaw street Unitarian Chapel, which contributed £639. Up to Monday evening the treasurer had been advised of collections amounting to upwards of £2000, and so far as can be ascertained the total amount promises to be a fair average of those of recent years.

THE PHYSIOLOGICAL EFFECTS OF PARACENTESIS.

THE physiological effects of tapping the abdomen in cases of ascites from atrophic cirrhosis of the liver have been studied by Dr. Gravirovski, who gives the details of his observations in a recent thesis for the degree of M.D. in the Medico-Chirurgical Academy in St. Petersburg. He found that the assimilation of nitrogen was increased by the operation, but that of the fatty elements of food was diminished; the metabolism of the nitrogenous principles was also increased, and the loss of albumen in the blood was soon compensated by the greater assimilative power for this nutritive principle. He comes to the conclusion, too, that more is gained by early than by late paracentesis.

EXPERIMENTS AT THE PHARMACOLOGICAL INSTITUTE AT DORPAT.

A RECENT volume of the Transactions of the Pharmacological Institute at Dorpat, edited by Professor R. Kobert, contains two experiments by Nicolai Kruskal, one on some combinations with saponin, and the other on the corn cockle (Agrostemma githago). The former partially concludes a series of experiments by the editor himself, and contains a number of new and important observations in chemistry, toxicology, and hygiene. Dr. Kobert had found that saponin, as described by various authors, especially the saponin extracted from quillaja bark, is not an elementary body, but a mixture of two substances, which are both poisonous, and which he calls respectively quillaja acid and sapotoxin. The researches of Kruskal are a valuable addition to our knowledge, as they have shown that the so-called saponins are a whole series of bodies, corresponding to several different general formulæ. Every series contains several members which, though they are identical as far as elementary analysis goes, and give the same chemical reactions, yet on pharmacological examination show a

Digitized by Google

marked difference in their toxic intensity. The sapotoxin of the corn cockle possesses a further physiological characteristic distinguishing it from all other kinds of saponin in the fact that it may be absorbed both by subcutaneous tissue and by the alimentary canal. The seed of the corn cockle contains, however, as is well known, besides its poison, a large proportion of nutrient matter, and attempts have therefore been made for many years past to introduce it as an article of food for beast and man. Such a use of the seed has become quite possible since Lehmann and Mori demonstrated that the poison may be rendered innocuous by the simple process of roasting the meal in iron pans. Natanson has also shown by his experiments in Kobert's laboratory that the non-poisonous kernel, which gives a particularly fine meal, is almost enveloped by the poisonous portion of the seed. The practical value of this question is best exhibited by the concluding paragraph of Kruskal's observations on his experiments on agrostemma. He informs us that the Russian military authorities permit the purchase of bread containing an addition of half per cent. of corn cockle, so that the soldier, in his daily ration of 1200 grammes of bread, takes 6 grammes of it, a quantity which may have a seriously toxic effect.

INFLUENZA IN ITALY.

AT Milan one hundred and five deaths from influenza between Saturday, the 2nd inst., at 4 P.M. and Sunday at 4 P.M., were registered on the latter of these days. The registration office is hardly equal to the task of entering the cases reported to it; funeral carriages are insufficient in number; and the gravediggers at the cemeteries, in spite of repeated reinforcements, are still calling for more hands. The Ospedale Maggiore is filled to repletion, and the same is announced from all the branch hospitals and lazarettos. At Como the mortality is almost as high, though, singularly enough, at the resorts on the lake itself the disease is inconsiderable. At Venice scarcely a family has escaped, and most of the public offices have their *personnel* reduced by one-half. At Bologna the malady is equally diffused, though the mortality is not so great in other cities. At Rome it is spreading, several thousand cases occurring daily, and in the Carceri Nuove (new prisons) four-fifths of the inmates, convicts and keepers, are on the sick list. Hitherto, however, the deaths have been comparatively few. Florence, which suffered so severely in 1890, has proportionately few cases, and these comparatively mild.

NEW RESEARCHES ON VARIOLA VACCINE.

IN connexion with the commission now being held on the efficacy of vaccination Chauveau's experiments are interesting. An abstract of them is given in the *Boston Medical and Surgical Journal* for Dec. 3rd, 1891. His experiments were made with the product of the eighth transmission from heifer to heifer, and were exclusively performed on subjects of the bovine species. The results of his investigations are briefly as follows: 1. Vaccine virus never gives small-pox to man. 2. Variolic virus never gives vaccinia to the cow or horse. 3. Vaccine is not even attenuated small-pox, and cannot be compared to the benign anthracoid infection which is communicated to animals by inoculation with attenuated anthracoid virus. 4. If vaccinia is a derivative of small-pox, it is by reason of a radical transformation of the variolic virus, a transformation thus far unattainable by experimenters. 5. These last propositions lead to another more general one, which is this: the attenuation of virus is not a physical process which can be identified with the transformation of virus. If these views are correct it may very naturally be asked, How does vaccine virus confer immunity from small-pox? On consideration of the results of experimental preventive inoculation we may divide them into three methods, as follows: (*a*) Fabrication of prophylactic substances by pathogenic agents outside of the organism which is to be rendered immune, and the introduction into this organism of the said substances in sufficient quantity to confer immunity, these substances having been by the proper manipulations freed from the virulent elements, properly so-called, and rendered inoffensive. (*b*) Fabrication, in the organism to be protected, of prophylactic substances by the pathogenic agents, with the germs of which inoculation has been made under conditions which ensure the benignity of their infectious effects. (*c*) Fabrication of the vaccinal substance by a virus very like the virus against which immunity is sought, but belonging to another species. In this latter category Chauveau places the microbe of chicken cholera, in its function of conferring immunity against charbon. Here also he would place the virus employed as a preservative from small-pox. Whatever, in fact, may be the origin of vaccine, though we were to admit it to be a derivative of small-pox, it none the less constitutes in reality a morbid species distinct from the latter. The two viruses—vaccinal and variolic—are irreducible into one and the same infectious entity.

DESTRUCTION OF THE CUNEUS.

A CASE in which the cuneus on one side was destroyed with almost the accuracy of a physiological experiment is related by Dr. Eskridge in the *Medical News* (Philadelphia). The patient was a strong and healthy man, who had received a bullet two and a half inches in front of the occipital protuberance, and half an inch to the left of the middle line. It was extracted a few hours after the accident, and was found lying just beneath the cortex. Two days later there was right homonymous hemianopsia up to the middle line, but the pupils reacted normally and the fundi appeared healthy. Mentally the patient was dull and slow, and he gradually sank into coma, and died on the fifth day. At the necropsy the wound was found healthy, but a good deal of hæmorrhage had taken place about it. The wound in the brain was two inches in diameter. Behind, it extended to within an inch and a half of the tip of the occipital lobe. On the median surface a thin layer of brain substance remained, slightly thicker anteriorly than posteriorly. The cuneus was in fact almost completely destroyed; and while the superficial part of the angular gyrus was uninjured, there was some damage to a part of its substance beneath the surface. The case is interesting as lending support to the view that the cuneus of one side represents the half of each retina on the same side, and consequently the opposite half of each field of vision.

SUBCORTICAL LESIONS AND SPASTICITY.

IN the *American Journal of Nervous Diseases* Dr. C. K. Mills records a case of some interest and one which supports the view that an extreme spastic condition of the limbs is usually associated with a subcortical brain lesion. The patient was a man who two or three years before he came under observation had an attack in which he lost the use of his right arm and leg. He did not become unconscious, but he was never able to stand afterwards. About a month later he had a fit commencing in the right arm during which he lost consciousness. Subsequently he had several similar attacks. He had some tremor of the tongue. The faradaic and galvanic irritability of the muscles on the affected side were retained. The knee-jerk on the right side was much exaggerated, and there was foot clonus, but the most persistent and marked symptom was a continuous spasticity of both arm and leg, especially the latter, on the paralysed side. He died of a hæmorrhage into the right hemi-

Digitized by Google

sphere which burst into the lateral ventricles, but the condition of the left hemisphere, which gave rise to the old attack, and was the cause of the paralysis of the right arm and leg, was the most important. To external examination nothing was evident except a dark spot, about one-fifth of an inch in diameter, at the bottom of the upper extremity of the central fissure, but on exploring the lateral ventricle a yellowish black area one-third of an inch in length was noticed in the white substance composing the curved roof of the ventricle, about the middle of its antero-posterior extent. This was found to be a hæmorrhagic cyst, lying in the part of the sub-cortex related to the middle and upper thirds of the anterior central convolution, and it was an arm of this cyst which extended to the spot of degeneration already described in the fissure of Rolando. Dr. Mills records the case as lending support to the idea that the predominant symptom in cases of subcortical lesion is persistent tonic spasm, and that a lesion such as existed in this case—partly destructive and partly irritative—has such a condition as its most characteristic accompaniment.

IODINE INJECTIONS IN MALIGNANT PUSTULE.

DON A. M. AYUSO publishes in *El Siglo Médico* three interesting cases of malignant pustule, which he successfully treated by means of hypodermic injections of iodine. In two of the cases the seat of the affection was the neck, which is usually considered a particularly dangerous situation. In one of them, indeed, there were symptoms of pressure on the larynx. In both cases incisions and powerful caustics had been previously applied without appearing to have any effect before the iodine treatment was resorted to on the fourth day from the commencement of the symptoms. The pure tincture was used in one case, while in the other it was diluted to half strength. The injections were made around the tumour at intervals of from two to three centimetres, and were not repeated. In a third case, which was that of a little child, the solution used was composed of four parts of the tincture of iodine, one of iodide of potassium, and eight of water, about seventy-five drops being injected altogether around the pustule, which was situated on the forehead. In this case and in one of the others an attack of convulsions followed the injections. Notwithstanding this, Dr. Ayuso is in favour of giving the injections of a considerable strength, so as to kill the virus at once. The needle should be inserted to the depth of from two or three centimetres in the œdematous zone bordering upon the indurated tissue. It is well, too, to press the piston of the syringe down at once rather than gradually.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Professor Jolly has been made a Medical Privy Councillor. Dr. Strassmann has taken temporary charge of the Pharmacological Institute. Dr. Hans Thierfelder has been recognised as *privat-docent* in Chemical Physiology.

Breslau.—Professor Kast of Hamburg has been offered the Directorship of the Medical Clinic, in succession to Dr. Birmer, who is retiring on account of his health.

Halle.—Dr. Bunge will probably succeed Professor Alfred Graefe, who is retiring, and to whom he has been for many years principal assistant.

Kieff.—Dr. Yakimovich has been promoted to an Extraordinary Professorship of Histology and Embryology.

Pavia.—Dr. T. Clivio has been recognised as *privat-docent* in Midwifery and Gynæcology.

Pisa.—Dr. F. Denti has been recognised as *privat-docent* in Ophthalmology.

Prague.—German University: Dr. F. Hueppe has been promoted to the Professorship of Hygiene. *Bohemian University:* Dr. F. Michl has been promoted to an Extraordinary Professorship of Surgery.

Rome.—Dr. E. Manara has been recognised as *privat-docent* in Ophthalmology.

Strasburg.—Dr. Jacobj has been recognised as *privat-docent* in Pharmacology.

Valencia.—Dr. Sloker y de la Pola, Professor of Anatomy, has been appointed to the Professorship of General Pathology.

Vienna.—Dr. Max Gruber has been promoted to the Ordinary Professorship of Hygiene.

Zurich.—Dr. Hugo Ribbert of Bonn has been appointed to succeed Professor Klebs in the chair of Pathology and Pathological Anatomy.

MR. ALBERT JAMES BERNAYS, Ph.D., Professor of Chemistry at St. Thomas's Hospital, who died on the 5th inst., at his residence, Acre House, Brixton, S.W., after a few days' illness from bronchitis, as already briefly recorded, was born in London in 1823, and was educated at King's College School and at the University of Giessen. He was Doctor of Philosophy of Giessen, Fellow of the Chemical Society, Fellow of the Institute of Chemistry, Lecturer on Agricultural Chemistry, 1845, and Lecturer on Chemistry and Practical Chemistry at St. Mary's Hospital Medical School, 1854-60. He had been Lecturer on Chemistry, Practical Chemistry, and Practical Toxicology at St. Thomas's Hospital since 1860; he was Public Analyst for St. Giles's, Camberwell, and St. Saviour's, Southwark; and late Examiner in Chemistry to the Colleges of Surgeons and Physicians. Dr. Bernays was the author of many works on Chemistry. He was cremated at Woking.

MANY officers of the Medical Staff will hear with great regret of the death of Brigade Surgeon Lieutenant-Colonel S. E. Maunsell, in the Jamaica command. The deceased officer had completed his tour of service and was about to embark for home, in anticipation of his early promotion, when he was attacked with yellow fever, of which he died. He was an excellent officer in every way, and enjoyed a considerable reputation professionally, more especially in ophthalmology. His skill as an operator was considerable, and he unostentatiously effected a large amount of good among the natives in the Umballa division of the Punjab, India, an account of which and other matters he embodied in a modest little work, entitled "Notes of Medical Experiences in India, principally with reference to Diseases of the Eye." Surgeon Lieut.-Colonel R. N. Malley has been appointed senior medical officer on the staff at Jamaica.

WM. CHARLES HENRY, M.D., F.R.S., who was a chemist and physician of great distinction, and for many years connected with the Manchester Infirmary, has died at the age of eighty-eight years. He was born on March 31st, 1804, took his academical degree at Edinburgh University in 1827, and spent some time in the study of medicine on the Continent. He was the author of certain works on the physiology of the nervous system, and of many papers and pamphlets relating to his studies in chemistry.

WE regret that, through an inadvertence, the name of Mr. Bryant, who attended as President and representative of the Royal College of Surgeons, was omitted in the account published in our last issue of Professor John Wood's funeral.

THE first session of the Congrès Périodique International de Gynécologie et d'Obstétrique will be held at Brussels, Sept. 14th to 19th, 1892. Mr. Alban Doran has been chosen to act as secretary for England.

THE death has been announced of M. de Quatrefages, the eminent ethnologist, aged eighty-two. He was author of "Crania Ethnica," and the standard work "Études des Races Humaines."

SIR ANDREW CLARK will resume his instructions in Clinical Medicine at the London Hospital on Tuesday, 19th inst., at 2 o'clock.

WELLINGTON COLLEGE SORE-THROAT.

BY J. G. BARFORD.

DURING the twenty-four years I acted as medical officer to Wellington College I had numerous opportunities of watching the progress of epidemic diseases as they affect schoolboys and the particular form of sore-throat occurring from time to time at Wellington College, which has puzzled the best physicians and surgeons of the latter half of the nineteenth century, from London and elsewhere, whom it was my privilege to meet and coöperate with from the first year of the opening of the College in 1859 to the end of 1883. But at no period of these twenty-four years does it appear that the boys have suffered in such numbers, nor, apparently from Dr. Bristowe's report, more severely than they have during the third term of the past year. The admission of 244 boys into the sanatorium, as stated in the report—that is, more than half of the school—is an occurrence, I believe, unprecedented in the history of the College. When it is remembered that the boys did not reassemble till the latter half of September and were dispersed at the beginning of December, the actual period of residence amounted only to ten weeks, making an average admission into the sanatorium of from twenty-four to twenty-five a week. The governors of the College express their satisfaction that, in the opinion of Dr. Bristowe, "the recent outbreak of illness cannot be attributed to defective drainage or water-supply, but rather to the almost unprecedented rainfall."

The chief importance of this sentence turns on the "almost," for it is a candid admission that there have been previous heavy rainfalls, but on these occasions the heavy rainfall has not been productive of the same illness or fatality among the boys. Three deaths in one year from diseases or their complications believed to be preventable, and which cannot be referred, according to Dr. Bristowe, to defective drainage or water-supply, are probably unprecedented in the history of our public schools. Is it possible that more or less rainfall can make this difference? I would ask, Can Dr. Bristowe be in earnest in leading the governors to entertain such an idea? Dr. Bristowe states in his book on "The Theory and Practice of Medicine" that "diphtheria is a disease of all countries and all seasons" (heavy rainfall or not), and that "there is reason to believe that the sanitary state of houses or localities, and the condition of health of those who are exposed to its poison, have much influence over its development." How can Dr. Bristowe reconcile the teaching in his book with the opinion he has expressed to the governors of Wellington College? I have read the article on Diphtheria in Dr. Bristowe's book (1884 edition), and cannot find a syllable on the influence of rainfall in the production of diphtheria. It is evident that Dr. Bristowe has attached no importance to rainfall in the past; or, as a lecturer on medicine and the author of a book on the "Theory and Practice of Medicine," he would have made some reference to it before. It appears to me most unfortunate for the reputation of Wellington College that Dr. Bristowe can find nothing further than this to explain the outbreak. Does the poison or germ which sets up diphtheria, in Dr. Bristowe's judgment, come down from the clouds with the rain to Wellington College? or is it that he would have us believe that the rainfall has some peculiar disturbing influence on the soil at Wellington College, creating it thereby into a cultivating medium for the poison which has recently presented itself in so virulent a form? Dr. Bristowe seems to me to be on the horns of a dilemma, and has to admit one or the other cause. Any theory he may have of the possible introduction of the disease from the village without is shaken by the fact that its occurrence in the College appears to be anterior to two cases outside the College grounds. In the past I have seen septic throats going on to diphtheria occur over and over again among the boys when no trace of the disease could be found among the residents outside the College boundaries. My twenty-four years' experience at Wellington College taught me that the boys conveyed infectious illness to the residents around rather than the reverse. Dr. Bristowe states that he cannot fix the date of the occurrence of the first case at the College; but if he will go into dates accurately he will find, I think, that the boys were infected before any case whatever occurred among the residents disconnected with the College. The Notification Act is in operation in the district, and definite information available for Dr. Bristowe. If he will go carefully into the notes, and especially the temperature charts, of each case admitted into the sanatorium during the term, he will have no difficulty in fixing the date of the first case in which the specific virus displayed itself. Anyhow, by this method I have in the past found no difficulty in fixing approximately the date of the first occurrence of septic sore-throat in the form it presents at Wellington College, which in the first instance does not present definite signs of diphtheria, for the diphtheria is engrafted on to septic throats as a secondary disease. A comparison of this approximate date with the date of the case first notified from the village would settle the point which Dr. Bristowe's report leaves so obscure. In his book he admits the elevation of temperature as a marked feature at the onset of this disease, and I find from the comparison of 100 charts that the temperature at the onset is very uniform. Here there is reliable data for comparison, of which he does not appear to have availed himself. The report leaves Wellington College uncertain as to the origin of a disease, and would teach that whenever the rainfall is in excess of an average, the inmates of Wellington College may have again to seek a home elsewhere.

(To be continued.)

INFLUENZA.

SELDOM in the records of previous pandemics of influenza has a third annual recurrence of this remarkable disorder exhibited such virulence as at the present time. Indeed, previous experience has mostly been to show that after the first outbreak the malady may recur in a more or less sporadic manner, and then disappear almost entirely. But there is no question now that the recurrence of this winter, which commenced in this country in Cornwall and in Scotland, has equalled in severity the first outbreak of the winter of 1889–90, as well as in the extraordinary diffusion of the disease which has taken place during the past fortnight. So widespread has this extension been that it is difficult and bewildering to follow its course from day to day, so as to give any coherent account of the progress of the pandemic wave.

There is no question that the influenza has once more gained a marked foothold in the metropolis. For weeks past, it is true, the Registrar-General's returns have given a certain number of deaths directly attributed to the disease, but last week this number rose remarkably, reaching 95, as compared with 37 in the preceding week, and 19 in the one before that. Medical practitioners are again overburdened with engagements, and nursing institutions are being taxed far beyond their resources. In Kensington an outbreak has occurred in the infirmary, just as last week at the Fulham Infirmary, and the disease is very prevalent in the neighbourhood. In the southern and western suburbs it is also rapidly extending, especially in Hounslow, Isleworth, and Ealing. Cases have occurred in the Hampstead Workhouse, and in the Chelsea and Wellington Barracks. The General Post Office departments, which suffered so severely two years ago, are again crippled by the sickness.

The general mortality of London for the past week was 32·8 per 1000, which is about the average for the past three weeks, the deaths referred to diseases of the respiratory organs amounting to 1084, or 455 in excess of the average.

In the home counties influenza is still very prevalent. It continues to spread in Berkshire and in Bucks; in Surrey it still persists in Chertsey and Walton; in Herts it is very

Digitized by Google

prevalent in Watford, and most severe in Kent and Essex. In these latter counties the outbreak seems to be especially virulent. Canterbury has suffered more than on the two previous occasions; and the agricultural as well as the urban communities in that district, and in and around Maidstone and Ashford, are also widely attacked. It prevails, further, in Chatham and Rochester, and still exists in Dover, Walmer, and other parts of the coast. In Essex it is generally prevalent, the villages on the coast suffering especially, but the epidemic has caused many deaths in Chelmsford, Colchester, Halstead, and other places.

In the southern counties, Sussex and Hampshire, especially Porchester, Portsmouth, and Southampton, have suffered severely; whilst in Dorset the outbreak has been attended with great fatality.

In Norfolk the epidemic has appeared at Norwich, King's Lynn, and many of the country districts; in Suffolk, at Lowestoft and Bury St. Edmunds, where the mortality has been very high. It is very prevalent in Cambs and Hunts, and in Northamptonshire, especially around Peterborough. At Leicester we are informed by Dr. Tomkins, the medical officer of health, that "for more than three weeks scattered cases of influenza have occurred, but only during the last week has it become at all prevalent, and at present the epidemic has not spread to anything like the extent of last year, nor is the type of so severe a character. Only one death has hitherto been reported." This mildness of type, which unfortunately has not been the case generally, is also noted in the outbreak at Birmingham and in South Lincolnshire.

In Worcestershire cases are very numerous at Kidderminster and its vicinity; in Staffordshire, at Tipton (chiefly among children) and Stafford and neighbourhood. Further north we find that the outbreak—which a month back was so prevalent in Newcastle—is now spreading through Yorkshire, especially around Richmond, Darlington, and Leeds; and it has appeared in Lancashire at Bolton and Liverpool. In Cheshire there is much sickness; and in Mold, in Flintshire, and other parts of North Wales.

The epidemic is subsiding in the towns and villages of South Wales—as at Cardiff, Aberdare, Carmarthen, Tredegar, and Abergavenny, but it still prevails in Monmouth. It has appeared in Bath, and still exists in an aggravated form in Somerset, Wilts, and Devon. Thus it will be seen that the disease prevails over the greater part of the country.

From Scotland it has practically disappeared. In Ireland it prevails at Limerick, Fermoy, and Baltimore. Of the Channel Islands, Guernsey has been the most seriously attacked.

The accounts furnished from the Continent show that influenza is still raging in many parts, and, indeed, in some towns—e.g., Hamburg—it has reappeared after a month's abeyance. In France it prevails in all parts, from the Pas de Calais in the North, where it is extremely severe, to Marseilles and the Riviera in the South, where its type seems to be milder. In Paris it continues to spread; at Montpellier it is largely on the increase. In Germany the epidemic has been present for several weeks at Berlin, where it is now on the decline, but where it has attacked the horses. At Munich it has only recently broken out, and is spreading rapidly. Of other cities where it has prevailed or is still occurring may be mentioned Kiel, Breslau, Dresden, Magdeburg, Brunswick, Stettin, and Cologne. In Denmark the outbreak has been especially severe; at Copenhagen itself the number of cases has been enormous, and the attacks have been characterised by great suddenness of onset. In Belgium it is very general, being severe at Brussels and Luxemburg, and seriously interfering with trade at Mechlin and Ghent. It is still causing great mortality in the lunatic colony of Gheel. In Austro-Hungary it still exists in Vienna, and at Pesth it seems to be unusually virulent. In Italy, where it has hitherto chiefly attacked the northern cities, it is spreading in Florence, Venice, and Rome, and is getting much worse in Naples. It has reached Turkey and Greece, for many cases have occurred at Constantinople and Athens. At Malta the Mediterranean Squadron has suffered severely from its effects. It has ceased to occur at Gibraltar, but prevails in many parts of Spain and Portugal, where, however, it is on the decline.

Across the Atlantic influenza is at present widely diffused over the United States, both in the north and south. It spread rapidly at the opening of the New Year in New York, Boston, and Philadelphia; has prevailed, but not with its former severity, in Chicago; and is especially rife at St. Louis, Kansas City, and Memphis. In Canada the type of the outbreak, which is now subsiding, has been mostly mild.

MEDICAL DEFENCE UNION, LIMITED.

THE Secretary of the Union sends us for publication the following report:—

A representative and well-attended meeting of the members of the Medical Defence Union was held at the registered offices of the company on Jan. 7th, for the purpose of confirming a resolution altering some of the articles of association. Mr. Lawson Tait presided, and in moving the confirmatory resolution explained that the proposed alterations, unanimously decided upon by the members on Dec 15th last after much deliberation, had been improperly described as a reconstruction of the company. They were nothing of the sort, but simply an example of an every-day occurrence of a company finding it desirable to alter some of its working rules, and doing so.—Dr. H. Woods opposed the resolution, and urged that the first meeting was technically illegal. In a short but censorious speech he reflected generally upon the President and Council, who, he said, sought to alter the articles in such a way as would enable them, if they thought fit, to decline to defend anyone but themselves and their friends; he referred particularly to the proposals as to election of the Council.—Dr. Saundby regretted that Dr. Woods saw things in a false light and in a way that the vast majority of his professional brethren did not and could not view them. The course Dr. Woods was adopting in the present instance was on a par with that which he had taken in connexion with the affairs of the British Medical Association and in other matters. It was an unfortunate attitude of mind which led him to impute *mala fides* to his colleagues on the simplest matters, and, after making unfounded assumptions against his professional brethren, to proceed to build up a casuistical superstructure thereon.—Mr. Lawson Tait, in reply, referring to the technical objection, pointed out that Dr. Woods had already been informed that the Court of Appeal, in a similar case, had decided the very point that Dr. Woods had raised, and decided it exactly opposite to his contention. The present proceedings were quite in order. The members of the Union perfectly well understood Dr. Woods; and that they were capable of managing their own affairs in their best interests was shown by the fact that, while two proxies only had been lodged in favour of Dr. Woods, more than 900 had been lodged in favour of the proposed changes.

The resolution was then put and passed, Dr. Woods alone dissenting.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Nottingham Urban District.—Dr. Boobbyer's report comes late, but the cause is one that will be appreciated, and especially in his own district. It is practically a second edition, in which he has utilised the returns of last year's census, and has thus dealt with the large statistical discrepancies which those returns divulged. The Registrar-General's estimate of the population of Nottingham turned out, in fact, to be no less than 40,233 in excess of the actual figures given by the census, and this accounts for a death-rate of 1·5 per 1000 higher than that which the estimated returns indicated; the real corrected rate for 1890 being 19·2 per 1000 living. The zymotic rate was low as compared with that for the large towns, being 1·8 per 1000, and it is reported that the new hospital at Bagthorpe, erected by the corporation, is now completed. During 1890, the notified cases of disease included 984 of scarlet fever, 348 of enteric fever, and 64 of diphtheria; and it is a somewhat remarkable fact that, in the case of scarlet fever, the percentage

Digitized by Google

of cases removed to hospital, which was only 12 per cent. of the known attacks in 1885, has steadily risen, until it reached 81 per cent. last year. Few things could afford a better testimony to the value and character of the work done towards the prevention of infectious diseases in the borough. To this may be added the information, that no less than 27,620 articles were submitted to a process of disinfection.

Birkenhead Urban District.—On a population which numbered 99,249 at the date of the census, the general death-rate for 1890 was 21·24 per 1000 in Birkenhead. Both as regards measles and the continued fevers there was excess of mortality as compared with the average, and the latter disease included typhus, of which sixty-four cases were notified. The total diseases notified were 2166 in number, and ninety-seven cases were removed to the very imperfect isolation hospital which has alone been available for so many years. Lately the subject of providing a hospital more adapted to the requirements of the borough has again been under consideration, and it has been referred to the Health Subcommittee for report. A large amount of disinfection, of current sanitary work, and a number of special inspections are referred to in Mr. Vacher's report; the subject of the housing of the labouring classes is receiving attention, and there is a proposal to deal with the midden refuse by destruction in a cremator.

Merthyr-Tydfil Urban District.—Mr. Thomas J. Dyke may almost claim the post of *doyen* in the public health service. He now submits his twenty-sixth report on the sanitary condition of Merthyr-Tydfil, a town where his labours have been followed by many improvements bearing on the health and comfort of the inhabitants. The population now exceeds 58,000, and during 1890 the death-rate was some 26 per 1000, as opposed to a mean of 23, influenza having contributed to the increase. Typhus appeared during the year; but by means of isolation, disinfection, and other precautions the disease did not extend beyond ten cases and one death. Enteric fever also caused some anxiety, and its distribution seemed to be associated with some pollution of water used in connexion with dairy processes. Reverting to his earlier labours, Mr. Dyke points out how, between 1845–55, the general death-rate for Merthyr was no less than 33 per 1000, and that when special groups of diseases are examined the diminution which has taken place is as striking as in the general rate. Deaths under one year of age, deaths from typhoid fever, and deaths from phthisis were at the rate of 80, 21·5, and 38 per 10,000 respectively; they now stand at 63, 3⅔, and 38 respectively. And whereas the average age at death was 17½ years, it has now been prolonged to 27½ years.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6862 births and 5612 deaths were registered during the week ending Jan. 9th. The annual rate of mortality in these towns was equal to 28·7 per 1000; in London the rate was 32·8, while it averaged 25·8 in the thirty-two provincial towns. The lowest rates in these towns last week were 15·7 in Croydon, 16·2 in Leicester, 16·6 in Bradford, 17·8 in Huddersfield, and 18·6 in Halifax; the highest rates were 35·0 in Wolverhampton, 36·0 in Portsmouth, 36·3 in Liverpool, 37·2 in Brighton, and 43·7 in Newcastle-upon-Tyne. The 5612 deaths included 549 which were referred to the principal zymotic diseases; of these 248 resulted from whooping-cough, 165 from measles, 44 from scarlet fever, 37 from diarrhœa, 32 from diphtheria, 23 from "fever" (principally enteric), and not one from small-pox. No fatal case of any of these diseases was registered in Brighton, in Plymouth, or in Huddersfield; while they caused the highest rates in Oldham, Sheffield, Cardiff, Newcastle-upon-Tyne, and Swansea. The greatest mortality from measles occurred in Liverpool, Cardiff, Gateshead, Newcastle-upon-Tyne, Norwich, and Swansea; scarlet fever in Halifax and Swansea; whooping-cough in London, West Ham, Sheffield, Swansea, Blackburn, and Oldham; and diarrhœa in Preston and Swansea. The mortality from "fever" showed no marked excess in any of the thirty-three towns. The 32 deaths from diphtheria included 25 in London, 2 in Sheffield, and 2 in Newcastle-upon-Tyne. No fatal case of small-pox was registered in any of the thirty-three large towns; four small-pox patients were under treatment in the Metropolitan Asylum Hospitals, and 1 in the Highgate Small-pox Hospital. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1435, against numbers declining from 1554 to 1471 at the end of the preceding five weeks; 104 new cases were admitted during the week, against 90 and 101 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 337, 553, and 1317 in the preceding three weeks, declined last week to 1084, but exceeded by 455 the corrected average. The causes of 122, or 2·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Croydon, Bolton, Blackburn, and in five other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Birkenhead, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 27·1 and 26·0 per 1000 in the preceding two weeks, further declined to 24·9 during the week ending Jan. 9th, and was 3·8 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·7 in Greenock and 22·2 in Perth to 30·5 in Dundee and 32·2 in Aberdeen. The 694 deaths in these towns included 22 which were referred to whooping-cough, 9 from measles, 9 from diarrhœa, 8 from diphtheria, 6 from "fever," 4 from scarlet fever, and not one from small-pox. In all, 58 deaths resulted from these principal zymotic diseases, against 41 and 69 in the preceding two weeks. These 58 deaths were equal to an annual rate of 2·1 per 1000, which was 0·7 below the mean rate last week from the same diseases in the thirty-three English towns. The fatal cases of whooping-cough, which had increased in the preceding three weeks from 12 to 22, were again 22 last week, of which 10 occurred in Glasgow, 5 in Aberdeen, 3 in Paisley, and 3 in Greenock. The 9 deaths from measles showed a further increase upon recent weekly numbers, and were all recorded in Glasgow. The fatal cases of diphtheria, which had been 4 and 11 in the preceding two weeks, declined to 8 last week, of which 5 occurred in Glasgow and 2 in Perth. The 6 deaths referred to different forms of "fever" showed a decline of 4 from the number in the previous week, and included 2 in Glasgow and 2 in Aberdeen. The 4 fatal cases of scarlet fever showed a marked decline from recent weekly numbers, and included 3 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 254 and 203 in the preceding two weeks, were 200 last week, and were 40 below the number in the corresponding week of last year. The causes of 79, or more than 11 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 29·1 and 45·8 per 1000 in the preceding two weeks, declined again to 35·0 during the week ending Jan. 9th. During the thirteen weeks of last quarter the death-rate in the city averaged 29·8 per 1000, against 20·5 in London and 25·5 in Edinburgh. The 235 deaths in Dublin during the week under notice showed a decline of 70 from the number in the previous week, and included 10 which were referred to whooping-cough, 5 to different forms of "fever," 1 to diphtheria, 1 to diarrhœa, and not one either to small-pox, measles, or scarlet fever. In all, 17 deaths resulted from these principal zymotic diseases, equal to an annual rate of 2·5 per 1000, the rate during the same period being 3·6 in London and 1·4 in Edinburgh. The fatal cases of whooping-cough, which had steadily increased in the preceding five weeks from 2 to 8, further rose to 10 last week. The deaths referred to "fever," which had increased from 7 to 10 in the previous three weeks, declined again to 5 last week. The fatal case of diphtheria was the first recorded in the city since November last. The 235 deaths registered in Dublin last week included 35 of infants under one year of age, and 72 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers in the preceding week. Seven inquest cases and 7 deaths from

Digitized by Google

violence were registered; and 37, or nearly 16 per cent., of the deaths occurred in public institutions. The causes of 24, or more than 10 per cent., of the deaths in the city were not certified.

INFLUENZA MORTALITY IN 1890.

The Registrar-General's fifty-third annual report recently issued deals with the mortality statistics of England and Wales for 1890. The report specially refers to the recorded mortality from influenza. It appears that the total number of deaths directly referred to influenza in 1890 was 4523. It is pointed out, however, that this number gives no trustworthy indication of the true mortality from influenza, since an unknown but certainly large proportion of the deaths due to this epidemic are invariably returned under bronchitis, pneumonia, and other similar headings. The first epidemic of influenza since 1837, when civil registration of deaths was established in this country, occurred in 1841, whereas the most fatal visitation was that in 1847, which lasted into 1848 and 1849; the disease also showed fatal prevalence in 1851, 1853, and 1858, whereas it did not figure conspicuously in the death register after 1858 until 1890, although the outbreak really commenced in the latter part of 1889. As regards 1890, however, the epidemic, which in London began to subside before the end of January, had, generally speaking, disappeared from all parts of the country by the end of March. With regard to the enormous increase in the mortality returned under other headings, especially under pneumonia and bronchitis, it is pointed out that it could not be attributed to the usual cause of increase under these headings—namely, low temperature—since the mean temperature of January, when the epidemic was most fatal in London, was 6·8° F., and that of the whole first quarter of the year 2·5° F., above the average. On the presumption "that the increased mortality from pneumonia, bronchitis, and diseases of the organs of circulation, compared with the average of the nine preceding years of the decennium, was due to the same cause as were the deaths directly ascribed to influenza," the number of deaths due indirectly to influenza is calculated to have been 22,551, which, added to the 4523 directly referred to the epidemic, raises the total mortality directly and indirectly due to influenza from 4523 to 27,074, equal to 941 per million persons living. The tables in the report under notice show that of the 4523 deaths ascribed to influenza 2415 were of males and 2108 of females; the disease was most fatal among males aged from fifty-five to sixty-five, whereas the most fatal incidence among females was during the age period sixty-five to seventy-five.

THE SERVICES.

ARMY MEDICAL STAFF.—Surgeon-Colonel W. Collis has been selected for the appointment of Principal Medical Officer to the troops in Ireland; Surgeon-Major-General Sir James Hanbury, M.B., F.R.C.S.I., having attained the age of sixty, has been placed on retired pay; Surgeon-Major-General Duncan A. C. Faser, M.D., is placed on retired pay (dated Dec. 27th, 1891); Surgeon-Lieutenant-Colonel Richard M. Craig retires on retired pay (dated Jan. 13th, 1892); Surgeon-Major John E. V. Foss, M.D., is placed upon temporary half-pay on account of ill-health (dated Jan. 12th, 1892); Surgeon-Captain M. T. Yarr, has been selected for temporary attachment to the Coldstream Guards, vice Surgeon-Captain Philip H. Whiston, who has accepted employment with the Egyptian Army.

NAVAL MEDICAL SERVICE.—The following appointments have been made at the Admiralty:—Surgeon Michael OBrien, M.D., to the *Northampton* (dated Jan. 9th, 1892); Surgeons and Agents: Mr. Henry Guy-Edwards to Bangor, North Wales, and Mr. James Trant to Knightstown and Port Magee (both dated Jan. 9th, 1892).

VOLUNTEER CORPS.—*Rifle:* 2nd Volunteer Battalion, the Duke of Cambridge's Own (Middlesex Regiment): Henry George Gastrill Wilkins, Gent., to be Surgeon-Lieutenant (dated Jan. 9th, 1892).—2nd Cadet Battalion, the Queen's (Royal West Surrey Regiment): Acting Surgeon C. S. Smith resigns his appointment (dated Jan. 9th, 1892).—1st Cadet Battalion, the Royal Warwickshire Regiment: Acting Surgeon F. W. Underhill resigns his appointment (dated Jan. 9th, 1892).

Correspondence.

"Audi alteram partem."

THE TREATMENT OF CHLOROFORM ACCIDENTS.

To the Editors of THE LANCET.

SIRS,—In your annotation upon the case of chloroform poisoning at the Middlesex Hospital I find that amongst the very numerous methods resorted to by the administrators in their efforts to restore animation there is no mention made of galvanism. This omission induces me to place on record a case in which I believe life was saved by the application of the faradaic current. I was about to excise the upper jaw in a man aged thirty-seven for an extensive sarcomatous growth. Complete anæsthesia having been produced without unusual incident by means of ether, I opened the trachea, introduced a cannula, and plugged the fauces, as a preliminary step to the operation itself. My assistant, Mr. Harrison, who has had considerable experience as an administrator of anæsthetics, proceeded to maintain the narcotism by means of chloroform dropped from time to time upon a small piece of lint held in forceps near the tracheal opening. Very shortly, and before the operation had been commenced, the patient suddenly ceased to breathe, and at the same time became ghastly pale. Meanwhile his pupils did not dilate, and his heart was found to continue its pulsations, though in a feeble and slower manner. Dashing the face with a cold wet towel and Silvester's artificial respiration were at once resorted to, and perseveringly continued for some minutes—Mr. Teale of Leeds and Mr. Greenwood of Ossett, as well as my assistant, giving me all the help they could. Air went in and out of the tracheal opening with great freedom, but on ceasing our efforts the patient gave no sign of breathing, his chest remaining quite motionless. It was here observed that the heart's pulsations were feebler and fewer. When matters were thus becoming very serious the faradaic battery, which for many years past has always been kept in readiness in my operating room, was brought into use, one electrode being pressed upon the left side of the neck and the other beneath the lower margin of the ribs. In immediate response to the current the patient made a deep inspiration, and from that moment respiration went on without further interruption to the completion of the operation. A prettier experiment I never witnessed. I am, Sirs, yours faithfully,

Leeds, Jan. 11th 1892. T. R. JESSOP.

"THE BEARING OF RECENT BIOLOGICAL RESEARCH ON THE PRACTICE OF MEDICINE AND SURGERY."

To the Editors of THE LANCET.

SIRS,—In Dr. G. Sims Woodhead's article in your issue of the 2nd inst. on the above subject, he states that "they (Drs. Wood and Maxwell Ross) decided to use iodine as a local irritant," applying it "in the form of a ring slightly beyond that portion which is already affected" in cases of erysipelas, with a view to bringing more leucocytes and an increased amount of oxygenated blood to the affected tissues, and so enable them to withstand the attacks of the micrococci and to overcome them. And, further, he states that Dr. Alex. Miles has treated in this way a large number of cases of erysipelas with marvellously successful results.

This is certainly a very gratifying result from the practical application of knowledge derived by a process of induction from the study of biology and bacteriology, and I do not wish for a moment to insinuate that such results are not to be expected even in increased number in the future; but it is a very interesting fact that in the year of grace 1892 Dr. G. Sims Woodhead is presenting to us, as new and scientifically bred, a method of treatment which one John Higginbottom of Nottingham, and afterwards of London, published and practised in the year 1829, the only difference being that he employed as his local irritant nitrate of silver, and here is his prescription:—℞. Argenti nitratis, ℈iv.; aquæ, f. ℥ ss. M. I am indebted to Dr. E. H. Bennett, Professor of Surgery in the University of Dublin, for the date (1829) of the *second* edition of Mr. Higginbottom's "Observations on the Use of Nitrate of Silver.

Digitized by Google

In the third edition of "A System of Practical Surgery," by William Fergusson, F.R.S., published in 1852, speaking of erysipelas, he says on page 117: "I have myself little faith in those (local measures) which are said by some to check the progress of the disease in a sudden, specific, and mysterious manner, such as the free use of nitrate of silver—a practice first inculcated by Mr. Higginbottom of Nottingham—applied either on the inflamed surface, by way of dispelling the affection at once, or in the vicinity, to check its progress and prevent its extending further on the surface than the line marked out by the caustic." Again, in Billroth's "Surgery," New Sydenham Society's Series, published in 1878, we read on page 15, vol. ii.: "As regards local treatment, a variety of measures has been adopted in order to stay the spread of the erysipelatous inflammation, and to bring it to a standstill. For this purpose the margin has been painted with a solution of nitrate of silver, or with a strong solution of iodine." Here we have Dr. Woodhead's own remedy mentioned, and that, too, in a way that would lead us to think it was an old—nay, a decrepit—remedy; for later on Billroth says: "According to my own experience, this is of no avail, so that latterly I have quite left off the practice." Mr. Erichsen, in his seventh edition of the "Science and Art of Surgery," vol. i., page 698, says: "A boundary line of nitrate of silver is occasionally drawn round the inflamed part with a view of checking the extension of the disease. I have often done this and seen it done by others, but never apparently with any benefit; and have now discontinued it as a useless source of irritation." So Mr. Erichsen speaks, too, in 1877, as though this treatment was as ancient, shall I say, as it was useless. Painting a ring with either nitrate of silver, tincture of iodine, or liquor ferri perchloridi fortior (B. P.) beyond the margin of the area of inflammation in cases of erysipelas was frequently mentioned as one of the suggested methods of treatment, both in lectures and at the bedside, in Dublin; and I remember the late Dr. Thomas Evelyn Little, whose opinion on matters surgical was greatly valued then, spoke highly of the use of nitrate of silver in this way, but the general impression was that the treatment was useless. It was my recollection of this procedure being spoken of as very antiquated indeed that caused me to look the matter up, when I saw it, to my surprise, set forth as a boon from the bacteriologists.

It is a curious example of the truth of the saying, "There is nothing new under the sun," and if it is such a wonderful remedy as Dr. Alex. Miles' results will doubtless (when they are published) lead us to suppose, it should make us have more respect for an empiricism that can find and lay aside as useless a mode of treatment which science disinters only after a lapse of sixty-three years, and then fondly imagines it has originated. In conclusion, I trust Dr. Alex. Miles' experience with his iodine will be more hopeful than was that of Fergusson, Billroth, and Erichsen with it or nitrate of silver. Mayhap the leucocytes have so benefited by the strides of science during the past sixty-three years that, knowing now what is expected of them, Dr. Alex. Miles' iodine will act upon them as a red rag is said to act upon a bull. I am, Sirs, yours faithfully,

LEONARD G. S. MOLLOY, B.A., M.D. Univ. Dub.

Blackpool, Jan. 6th, 1892.

THE COUNTY INFIRMARIES OF IRELAND.

To the Editors of THE LANCET.

SIRS,—I notice that a short time ago a deputation from the surgeons of county infirmaries in Ireland waited upon the Chief Secretary for the purpose of reminding him of the necessity of providing in the coming Irish Local Government Bill some sort of protection for these institutions against the anticipated determination of the popular party (who will form the chief power in the projected County Councils) to disestablish and disendow the infirmaries. With the administration of these hospitals I have nothing for the present to do; but it seems to me an opportune time to point out that provision should be made in the coming Bill for the amalgamation of county infirmaries and the workhouse hospitals, for once we get an Irish Local Government Bill the fate of the hated workhouse is sure to be sealed.

The provision I would point out as being amongst those which any future Bill should contain would be such as I pointed out to the Lurgan Board of Guardians in January, 1888, when I brought forward a resolution calling upon the Government "to cause a searching inquiry to be held into the working of the Poor-law system with a view to its entire abolition, or such changes in it as would be more in accordance with the wishes of the people." In the course of my address in support of this resolution, I gave a brief outline of an alternative system, an idea of which may be gathered from the subsequent portion of this letter. Though the guardians neglected this resolution without adducing a single reason or argument against it, yet when I subsequently got the remarks I ventured to make in support of my resolution printed in pamphlet form, and sent a copy to most of the principal papers in the United Kingdom representing every shade of politics, every one of the papers I had an opportunity of seeing devoted leading articles to the subject, and criticised my remarks most favourably, and all were agreed that the Poor-law system at present in vogue demanded reformation. In the course of my address I pointed out that the poor in our workhouses might be divided into three classes; the lunatics I did not include, as they should be sent to the asylums proper. In the first class I placed the sick infirm—by infirm I meant those incapacitated by old age—and children under three years. For these I proposed that "Cottage Hospitals" or "Homes for the Sick and Infirm" should be established. In the second class I included children over three years and under thirteen years of age. These I suggested should be kept out at nurse, as at present. The third class embraced the casuals and able-bodied paupers. The relief of casuals I considered should be placed under police control, as they could better discriminate the dishonest, scheming, or idle but able-bodied paupers, and be in a position to detect criminals. My rule for them, I pointed out, would be "work or bread-and-water." The police could have tickets for lodgings and tickets for food, for which, on being presented to the lodging-house keepers, equivalents by the way of lodging and food would be given. These tickets could be purchased by charitably disposed persons and given away, but in each case the recipient would be required to present himself at the barracks to have the ticket stamped by the constabulary. For the others of this class I suggested we should do as the Americans do—viz., appoint work masters or superintendents of labour. Their duties would be more comprehensive than those of our relieving officers; they could keep registry offices for the unemployed and employers of labour. They should have power to afford provisional relief to those in distress or difficulty, or afford loans recoverable by an easy process at law. All this to be under the control of a small elected committee. Such is a brief outline of the system I suggested.

Now if such a system as the foregoing were adopted, those embraced in my first class—viz., the sick and infirm, as well as those treated in county infirmaries—could be housed in the "cottage hospitals" or "homes for the sick and infirm." Having pay wards attached to them, this would do away with the objections which those who are able and willing to pay have to enter the hospitals connected with the present workhouse. In any case I can see no reason for the coexistence of county infirmaries and workhouse hospitals. The voice of the people must be attended to, and the Poor-law system is bound to be reformed. With that reformation will, I hope, come the solution of the present difficulty in connexion with the county infirmaries of Ireland.—I am, Sirs, yours faithfully,

E. MAGENNIS, M.D., D.P.H., J.P.

Lurgan, Jan. 11th, 1892.

THE DUKES AND CARPENTER FUND.

To the Editors of THE LANCET.

SIRS,—I am pleased to see the action of the Croydon Medical Reading Society in coming forward so promptly and generously to the rescue of their unfortunate brethren, Drs. Dukes and Carpenter, who have innocently fallen into the pit prepared for them by the anomalies of the Lunacy Act. In some of its clauses for the extreme protection of the poor lunatic the red-tapeism of the Act borders on the ridiculous. Take, for instance, the written statement to be handed to the patient, signifying his right to be taken before a judicial authority. What an opportunity for a high-flown, imperious patient to excite himself and worry his attendants! While every effort is made to afford the lunatic protection, and to satisfy the suspicious public who are so jealous of the liberty of the individual, the safety, the dignity, and the convenience of the general practitioner are ignored or deemed

Digitized by Google

of small account. The lunatic is the point to which all kinds of public sympathy—mistaken, misdirected, and sentimental—converge. He is the precious individual to be fenced in by the tangles and barbs of a fearful and wonderful piece of legislation. The numerous protecting arms of sections, clauses, and enactments are his shelter from the designing knaves interested in his confinement in an asylum or elsewhere. But the only defence of the medical man bold enough to put his name to a lunacy certificate is a gingerbread fabric, which any aggrieved lunatic, especially when backed by mischief or misdirected zeal, can easily knock down.

It is perfectly right to remind Drs. Dukes and Carpenter that there is such an institution as the Medical Defence Union, and to point out the folly of not having joined it. Let us, however, give them the help first and the lecture afterwards. I may add that Drs. Dukes and Carpenter are personally unknown to me, and that my interest in their behalf arises simply from a strong sense of the injustice and wrong to which they have been subjected, and of our obligation as members of a noble profession to help one another in trouble.

I am, Sirs, yours obediently,

West Norwood, Jan. 9th, 1892. J. A. AUSTIN, M.D.

LONDON CONSULTANTS AND GENERAL PRACTITIONERS.

To the Editors of THE LANCET.

SIRS,—In the somewhat fitful and discursive correspondence on the above subject, which has now been carried on for some years past in your columns without an apparently satisfactory conclusion having been reached, some points have been left out of sight which appear to me of importance, and should go far to settle this question amicably; and I therefore beg your insertion of the following lines. The general practitioners always assume that they confer unmixed blessings on the consultants, but receive none in return from them, and are, in fact, treated with the blackest ingratitude. They entirely forget that if the consultant benefits by the practitioner, the latter benefits quite as much by the former. Thousands of patients are annually sent down to the country and seaside by London consultants, with introductory letters to local practitioners, who attend to those patients sometimes for months together. Not only this, but the consultant often recommends friends of his, who may be off and on his patients, to a particular practitioner, when they go to live in one of the suburbs or out of town. I have frequently found, after having done so, my friends so satisfied with the choice I had made for them that I have never seen them again professionally. Let us, therefore, cease squabbling, and adhere cheerfully to the right principle of "give and take," which, when carried out consistently and without any afterthought, is sure to lead in the end to the satisfaction of both sides.

I am, Sirs, yours faithfully,

Harley-street, W., Jan. 4th, 1892. A LONDON CONSULTANT.

EPIDEMIC INFLUENZA.

To the Editors of THE LANCET.

SIRS,—It is now over a decade since I wrote you a letter under the title of "Medicus." The circumstance was the obstruction I had in the completion of my observations on the epidemic fever of a peculiar type which, to my mind, then appeared much like the hunger pest. This was simply on account of the relapsing feature of the disease. The observations which I then began have been steadily kept up, and I am in a position to prove the continuity of repeated epidemics of the same fever at intervals of two and three years, until in 1888 it decidedly almost died out.

When the great pandemic of the epidemic influenza spread all over the world I made it a study to keep up to the literature of the disease, and it is some consolation to know that what others failed to show me has now been taught the world by the great scourge of 1889–90. I traced the disease to Afghanistan in 1882–83, and I feel sure that the epidemic fever of Calcutta found its way to Russia through the Caucasian track and revealed itself to the Western world, and was only then recognised as the epidemic influenza. I have the history and origin of the epidemic in Calcutta, and it will be an uncomfortable surprise to the world to know that the insanitary Gangetic delta in which Calcutta exists can develop such formidable epidemics.

A word with reference to the illness of Prince George of Wales. You will not consider me too bold if I say that I possess notes and clinical observations of similar cases in our epidemics to which I have alluded. The spots go for nothing. The great nervous prostration and the subnormal temperature, as well as the sweat, are characteristic of the remittent type of epidemic influenza cases. There are cases much like the typhus, too, and a variety of others. It is a protean disease, and in this the epidemic influenza is closely allied to that formidable disease syphilis

I am, Sirs, yours faithfully,

Calcutta, Dec. 23rd, 1891. MEDICUS.

ANTISEPTICS IN OPHTHALMIC SURGERY

To the Editors of THE LANCET.

SIRS,—I regret that I still fail to see the object of Dr. Bullar's experiment on the rabbit's eye; he surely must have expected the result to have been what it was—viz, that in a few days it stank abominably. He must have known the eye would not be prevented decomposing by a 1 in 4000 perchloride solution. Beef-steaks &c. have been kept sweet and free from decomposition for many weeks by the antiseptic method, but by stronger measures than a 1 in 4000 solution of perchloride. I do not wish to push the matter too far, but I contend a living human eye *can* be operated on and dressed afterwards perfectly well in a way more likely to destroy germs, and also to exclude them, than the method adopted by Dr. Bullar with his rabbit's eye. Many surgeons dress the eye after cataract extraction with a thick and elastic layer of sublimate wool, which is frequently impregnated with a 1 in 500 corrosive sublimate. I fancy a germ would find it no easy matter to dodge through the interstices of a couple of inches or so of ordinary cotton wool, and the addition of the sublimate would not lighten his exertions.

We must, I think, put Dr. Bullar's experiment aside; for all practical purposes it is useless. The only method left to us is by comparing results, as Dr. Bullar has himself suggested. To that method there are also objections, but there can be nothing perfectly free from objections. Personally, I very much wish the matter could be decisively and once for all settled, and that the conclusion would be adverse to all antiseptic methods; what a lot of time and trouble it would save us! I have seen, and frequently seen, what Dr. Bullar would, I believe, admit to be a very fair sample of ophthalmic surgeons operate—viz., the staff of Moorfields hospital, where I was a clinical assistant off and on for about three years, Professor Fuchs of Vienna, the ophthalmic staff of St. Thomas's Hospital and of the Edinburgh Infirmary, and Dr. Bell Taylor, and all to a man use antiseptic methods, or did so when I last saw them. I admit that does not prove there is anything in the method, but it is suggestive at least. Most of these operators are old enough to have experienced the pre-antiseptic age; but somehow, after a pretty fair trial, they do not seem to give up antiseptic precautions. It may not be a point quite on the same level, but if Dr. Bullar had to operate straight off on a cataract with a mucocele on the same side, which method, the antiseptic or the other, does he think would give that eye the best chance? In conclusion, let me assure your correspondent it is not my intention to engage in wordy warfare with him or anyone else on the antiseptic or any other system; it is so easy to criticise, so difficult to construct. This correspondence is closed so far as I am concerned. I only hope some practical outcome of Dr. Bullar's suggestion may be reached ere long, and few things would gratify me more than to feel assured that the antiseptic method—not our civilisation—is a failure, it would save no end of bother. At present, I reluctantly admit, I cannot think so.

I am, Sirs, yours faithfully,

S. JOHNSON TAYLOR, M.B., M.R.C.S.

Norwich, Jan. 11th, 1892.

PERCENTAGE OF FIBRIN IN THE BLOOD OF LEPERS.

To the Editors of THE LANCET.

SIRS,—Dr. Beaven Rake states in the current number of THE LANCET that he has found the amount of fibrin in leprous blood much increased; in some cases the percentage found being as much as seven or eight times the normal. Without wishing to dispute the general conclusion at which he has arrived may I be permitted to point out the rough

Digitized by Google

method of analysis that he has adopted. If Dr. Rake has further opportunities of prosecuting his research I would suggest that he might adopt a method by which his results can be more accurately compared with those obtained from normal blood which he quotes. The particular points to which his attention should be directed are: (1) Soaking fibrin in water for some hours is not sufficient to free it from corpuscles (it is better to place it under a running stream of water, kneading it frequently in order that all parts of the coagulum are exposed to its action); (2) fibrin dried on blotting-paper cannot be accurately spoken of as dried fibrin—dried fibrin is fibrin which has been exposed in a hot-air oven at 110° C. for some hours until it loses no further weight from evaporation of water; (3) after this the mineral admixture has still to be deducted, this being ascertained by weighing the ash left after ignition.

I remain, Sirs, yours truly,

King's College, Jan. 9th, 1892. W. D. HALLIBURTON.

THE ROYAL MEDICAL BENEVOLENT COLLEGE.

To the Editors of THE LANCET.

SIRS,—I thank you for your notice of the claims of the Royal Medical Benevolent College at Epsom for professional and public support. Since speaking at the festival in 1890, I have been advised that if I can now collect £26,000, and can show a strong subscription list for the foundationers, in addition to a good, sound, successful school, I shall have but little difficulty in obtaining an amended Act of Parliament to secure the benefits we desire for our pensioners. In doing this great charity to the aged, we shall be doing an incalculable good to the school, to foundationers, as well as to the sons of medical men or other boys attracted to the College by the excellent education we offer.—I am, Sirs, yours faithfully,

C. HOLMAN,

Reigate, Jan. 11th, 1892. Treasurer to Epsom College.

SHAKESPEARE'S DEATH.

To the Editors of THE LANCET.

SIRS,—With reference to the correspondence lately contributed to your columns respecting the cause of Shakespeare's death, let me be allowed to state that on two occasions on which I had occasion to witness the testament of soldiers affected with delirium tremens, or, as they themselves say, "delirium tremendous," both of whom, however, recovered, I was particularly struck with the resemblance of their signatures to that appended to the similar document of the great dramatist. I can see nothing disgraceful or unlikely in the fact that a retired poet, actor, and playwright in the age of James I., and much later, having died from a debauch, aggravated by the medical treatment in vogue down almost to our own times, and indeed not unusual within my own memory. Ben Jonson we know, from the testimony of Drummond, of Hawthornden, and other witnesses, to have been a habitual abuser of alcoholic stimulants. "Drink," says the above writer, "was the element in which he lived." And from other evidence, and even from his own doggrel, we know that Shakespeare, both in London and after his retirement to Stratford-on-Avon, had the reputation of being a boon companion. No doubt the disease *may* have been intensified not only by antiphlogistic medical treatment, but also by the malaria of an insanitary English village of the period. Marlowe's case is not dissimilar. I am, Sirs, yours truly,

R. LEWINS, M.D.,
Surgeon Lieutenant-Colonel.

Army and Navy Club, Pall Mall, Jan. 5th, 1892.

COMMUNICABILITY OF PHTHISIS FROM MAN TO LOWER ANIMALS.

To the Editors of THE LANCET.

SIRS,—A patient of mine, with a tubercular family history, died at the age of fourteen of acute tuberculosis. His two pets, a dog and a rabbit, which were often to be seen in his bedroom, and very frequently on his bed, died a short time afterwards of what appeared to be phthisis, a prominent symptom being a constant cough. A veterinary surgeon who examined the dog pronounced the cause of death to be consumption. From the facts stated I think it might fairly be inferred that the disease was communicated from the patient to the dog and rabbit.

I am, Sirs, yours truly,

J. ARMSTRONG, M.B. Edin.,
Late Senior Physician, Liverpool Infirmary for Children.

Liverpool, Jan. 12th, 1892.

REMOVAL OF THE GREAT TOE-NAIL.

To the Editors of THE LANCET.

SIRS,—I am frequently called upon to remove the great toe-nail by surgical operation. Till within the last year or two I have followed the usual method by dividing the nail down the middle with a pair of scissors, and tearing away each half separately with forceps. Of late I have adopted another plan, which I venture to recommend as much better. Observing, as all must have done, the readiness with which a splinter of wood inserts itself beneath the nail, I take a piece of ordinary deal lath about four inches in length, pare one end thin, and adapt it to the size and shape of the particular nail. The thin edge, previously oiled, is passed rapidly beneath the nail down to its root and the hand raised, thus completely detaching the nail from its bed in about two seconds of time. The advantages claimed for this simple operation are threefold—its extreme ease of execution, its rapidity, and the very slight injury inflicted on the soft parts. I am justified in recommending its adoption by the approbation of others who have tried it.

I am, Sirs, your obedient servant,

Benson, Oxon., Jan. 8th, 1892. A. G. FIELD, F.R.C.S.

SMALL-POX AT DEWSBURY AND BATLEY.

To the Editors of THE LANCET.

SIRS,—In an editorial note of last week's issue you comment severely on the inaction of the sanitary authorities in Dewsbury and Batley. I wish to put you right as far as Dewsbury is concerned. A corporation hospital for the reception of infectious disease was erected four years ago. All cases of small-pox occurring in this sanitary district, whether paupers or otherwise, are treated there. Your note anent the action of the guardians is not a whit too strong. I am, Sirs, yours truly,

Dewsbury, Jan. 11th, 1892. W. F. WATTS, M.O.H.

THE PREVENTION OF INFLUENZA.

To the Editors of THE LANCET.

SIRS,—The value of small doses of quinine as a prophylactic during outbreaks of influenza has been so marked in my hands, both in 1890 and at the present day, that I deem it worthy of extensive trial, and trust that it will prove itself in other hands as reliable a means of prevention as it has done in mine. I prescribe a three-grain sulphate of quinine tabloid to be taken daily at breakfast, and to be continued until the epidemic disappears from the locality.

I am, Sirs, yours truly,

Cannes, Jan. 6th, 1892. H. BLANC, M.D., F.R.C.P.

THE EDINBURGH ASSOCIATION FOR THE PROMOTION OF REFORM IN MEDICAL EDUCATION.

(BY A CORRESPONDENT.)

THIS Association has quite recently been called into existence by the fact that the draft ordinances in medicine issued by the Scottish Universities Commissioners are unsatisfactory and the reforms proposed by them inadequate. The Association consists mainly, but not entirely, of the younger men who are lecturing or teaching in the school, and also of graduates interested in the advancement of medical education; it also includes a few University assistants. Already the Edinburgh Colleges and the Association of Extra-mural Lecturers have presented statements to the commissioners which have in the main dealt rather with the relations of the intra-mural and extra-mural schools than with what might be regarded more purely as reform or advance in the methods of teaching and the curriculum of study. The members of the new Association are men who

Digitized by Google

are acquainted with the newer methods which have already been introduced into some of the English schools, and who recognise the importance of a thorough training in practical detail, and the absolute necessity of this side of medical education in the University being entirely remodelled if the reputation of Edinburgh is to be maintained. These were the circumstances and the motives which resulted in the formation of this Association.

The outcome, so far, of its deliberations is that a statement was prepared and sent to the commissioners at the end of the year. The statement is so important, and deals so directly with some of the faults of the present condition of things, that a somewhat detailed abstract of it will be interesting to many readers of THE LANCET, graduates of Edinburgh. It begins by stating that the number of students in 1870-71 was 678, and rose to 1603 in 1880-81. This increase is accounted for by the influence of distinguished teachers in the school, by the fact that in England the only entrance to the profession for the average student was by a college diploma, and by the Edinburgh school being distinguished for the excellence of the practical instruction given in it, and that in this last respect it was not surpassed by anything then obtainable in England. During the eighties the number of students continued to rise, and reached in 1889-90 to 2003. During the eighties no corresponding increase to the teaching power or adequate improvement in the medical curriculum of the University was made, notwithstanding the fact that, owing to public support, the medical school of the University had been accommodated in a building which it was anticipated would fulfil all modern requirements. As a result of the increase in the number of students, they were taught in systematic classes, sometimes of nearly five hundred, a condition under which it was of course impossible for the vast majority of students to see and personally examine the details of experiments or practical demonstrations, so that little practical value could be derived from the lecture over and above what could have been obtained from the well-written and easily accessible text-books issued in all the departments of medical science. At the same time the numbers attending the practical classes increased so greatly that satisfactory personal supervision by the authorised teachers became impossible. It is then pointed out that during this period changes took place in the English schools which it is not desirable to under-estimate—changes both in the extent of the English curricula of studies and in the methods and means of teaching. Some of these changes are referred to and need not be given in detail here, the point being that the tendency has been to minimise the number of systematic lectures and to extend in a marked degree the practical training. A table is given comparing the compulsory number of lectures and the number of hours of practical work a student has to attend to qualify for the Edinburgh and London Universities and the Victoria University. They are roughly as follows: Edinburgh requires ninety lectures more than London, and twenty less than Victoria; Edinburgh requires 200 hours of practical work, London 510, and Victoria 600. From this it is pointed out that the Edinburgh school, once distinguished by the prominence given to practical studies, is now being outstripped by its English competitors in this very particular. As regards the entry of freshmen, they have gone down from 590 in 1888-89 to 446 in 1890-91, while London has gone up from 980 in 1888-89 to 1097 in 1890-91. The statement goes on to say that in view of these facts it was hoped that some thorough and far-reaching plan of reform would be introduced into the University, but that no measure of reform is introduced which in the opinion of the Association is at all sufficient to save the future of the Edinburgh school.

The statement then suggests the line of reform which ought to be followed. It is not proposed to suddenly raise the standard of the ordinary degree, but to materially improve it in various ways and to introduce an honours school. By this means it is thought that the men who are content with the pass examinations will be retained in the school, while it would also attract and keep the more ambitious and capable men. By an honours' school is meant one in which an extended training is given and an extended knowledge is required in some or all of the subjects of the curriculum. Then follow specific suggestions regarding the pass degree. The present system of dictating lectures is animadverted on, and it is suggested that a syllabus of the requirements for the pass degree should be issued so that the task allotted to the average student would be reasonably within his powers. It is also recommended that the number of systematic lectures in all the departments might be materially reduced. Materia medica has been placed in the draft ordinance in far too prominent a position, and the Association consider it a mistake to make practical pharmacognosy and pharmacy the sole subjects in the second professional examination (or any other special examination) of students who in their after-life will, as a rule, be largely relieved by the retail druggist from the consideration of such subjects. They also suggest that the number of lectures on this subject should be reduced from 100 to 50. It is further deemed essential that the first three years be devoted to the study of the medical sciences, including pathology and materia medica, and that the last two years be retained for the subjects of the final examination, the last year being kept as clear as possible for clinical work. The extension of practical teaching is then dealt with, and its importance impressed upon the Commission; and it is suggested that the difficulties in carrying out improvements in this direction might be facilitated by recognising the extra-mural teachers. Meanwhile they make the following suggestions: In natural history they advocate the institution of an improved "educational museum"; in it, botany and chemistry, the number of lectures should be reduced and the practical teaching extended, and they might be specially adapted to the requirements of students of medicine. In anatomy, that the number of lectures be reduced to eighty, and such subjects as the detailed anatomy of bones and muscle insertions be relegated to a junior teacher, who would demonstrate them to small classes. In physiology, that embryology be discontinued as belonging to anatomy, and that histology be left to the class of practical histology, and that a more extended course of chemical physiology be instituted, with ten additional hours for simple experimental work. In pathology, that, as in the other subjects, the lectures be reduced in number and increased facilities be given for naked-eye pathology, and attendance for three months at the post-mortem theatre should be insisted on. In medicine and surgery, in addition to curtailing the number of lectures, short courses should be given on the eye, ear, and throat, diseases of children, &c. In midwifery, that fifty lectures be devoted to obstetrics and thirty to gynæcology, and in addition ten or twelve practical demonstrations. That a course of fifty lectures and demonstrations be given on medical jurisprudence and toxicology, and a separate course upon public health. And lastly, that all practical classes should be limited by the University Court to such number of students as, in their opinion, an experienced teacher can efficiently teach.

Then follow suggestions respecting the proposed honours school. While admitting that there might be differences of opinion as to the details of such a school, the reformers hold that the candidates should pass through a more extended practical training. In the first professional examination the candidate might present himself for honours in natural history and botany, or physics and chemistry; in the second examination, in anatomy or physiology; in the third, in pathology, including practical bacteriology, or materia medica, including pharmacology; while in the final, he would have to present himself for honours in medicine, including diseases of children, tropical diseases, insanity, medical ophthalmoscopy, and medical laryngology; or surgery, including operative surgery, the eye, ear, and throat; or in midwifery, including gynæcology and abdominal surgery. In order to graduate in the honours school the candidate would require to select for honours one department in the final examination, and any three departments in the previous part of his course, but he must attend the whole of the classes of the honours school and undergo pass examinations in those subjects which he does not select for honours. The statement dwells upon the importance and necessity of introducing new subjects, and also of having more advanced classes in the subjects already taught and required for examination. The Association further urges the necessity of a largely increased staff of examiners. In their opinion the present number of examiners is totally inadequate, and as a result the examinations are not carried out with due care and deliberation. In conclusion, the Association assure the commissioners of their conviction that improvements on the lines suggested by them would meet with general acceptance. The plan of reform indicated would remove defects which have long been acknowledged and would enable the University to maintain its position among the foremost medical schools.

THE PSYCHOLOGICAL MUSEUM AT FLORENCE.

(FROM OUR OWN CORRESPONDENT.)

TO-DAY in the Reale Istituto di Studi Superiori was inaugurated the Museo Psichologico collected by the distinguished biologist and man of letters, Professor Paolo Mantegazza. There was a large attendance of the scientific, literary, and artistic worlds—medicine being numerously represented—while a prominent figure was that of the Commendatore Luigi Borg de Balzan, to whose liberality are due not only the donation which enabled Professor Mantegazza to add to his collection, but also the permanent fund which will help still further to enrich it, and to maintain the museum itself, with all its *personnel*, for the use of the public, professional and non-professional.

The museum is replete with objects of every conceivable kind, which serve to illustrate the play of the sentiments and passions of every people, in every age. The most savage races are not left out, and the implements connected with their religious worship, as well as the armoury of torture, of personal vanity, of voluptuous pursuits of all kinds, form the starting-point of an ascending scale of psychological manifestation culminating in the latest fads of the *fin de siècle* school.

Professor Mantegazza did the honours of the inauguration, and in the course of his address explained the idea that underlay the project now put into shape. "The Museo Psichologico," he said, "is a collection of every article and document that can throw any light on the genesis and evolution of human passion, exclusive of the ethnological element. While in the museum of ethnography we have the manifestation of thought, of art, of industry among all the peoples of the world, we aim at representing in this museum the facts which illustrate the individual varieties of psychical development in health and in disease. The question to be solved was one of method in the arrangement of *matériel* rather than of the *matériel* itself. For in science the question of method is not less important than the question of subject matter. I would like to see a 'Museo d'Etnografia' arranged in the psychical order and not in the ethnological order, and certainly the same things disposed on a different system would speak differently to our minds. Instead of seeing in the compartment devoted to Australia, for example, how the Australians clothe and feed, how they hunt and slay, we should find in one hall everything that bears upon the vesture of all peoples, in another everything that illustrates the chase, war, and so forth. This psychical arrangement was already tried and to a partial extent carried out in some museums; but the majority of ethnologists prefer the geographical or ethnological system, because more convenient, more easy, and more comprehensive. I, too, in my 'Museo d'Etnologia' debated long with myself as to the method I should adopt in the arrangement of my collection, and I chose the geographical.

"There are, however, many objects which refuse to be classified under the geographical or the ethnical relation, and which I wished to gather together as a first nucleus—as first specimens—of a psychological museum. I present some of these to you now: a hair shirt (of penance); a pack of cards fabricated by galley slaves for secret gaming; a Corsican stiletto (for *vendetta*); the necklace of a woman of the Andaman Islands, made with the bones of her infant boy; the jaw-bone of another boy, worn as a bracelet by a woman of New Guinea. Every department of my psychological museum will in time illustrate in this way the passions or sentiments of mankind. In the department of love you will find amatory offerings, instruments for safeguarding the purity of the female sex, love philtres, and such like. In that of pride will be exhibited the insignia of power, of social class distinctions, and court decoration. In that of religious sentiment we shall have on view the amulets, the idols, and the vast diversity of the *matériel* of different cults."

Professor Mantegazza concluded by declaring the museum open to the public, and may be congratulated on having added another to the many attractions of Florence.

Florence, Dec. 28th, 1891.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Influenza in Northern Counties.

I BELIEVE that since the cholera epidemic there has never been such illness or mortality in the north of England as at the present. In Richmond and the surrounding villages it is computed that there are over 1000 cases, and many deaths have taken place. At Middlesbrough, the medical officer of health, Dr. Malcomson, reporting on the sudden rise of the death-rate, said the cause had been twofold—viz., the exceedingly inclement weather experienced about the middle and latter part of the month, fogs and severe frosts prevailing, and the return in a very virulent form of the influenza, so that the mortality was greatly out of the ordinary proportions amongst infants and old persons. It might, Dr. Malcomson said, "be taken as a general truth that cold killed the infants, and the influenza and its complications were fatal to the aged," and he thought that there was no doubt that many of the deaths under other heads had their starting-point in this malady. It was pointed out by a speaker at the Sanitary Committee that there was also at present a large amount of destitution in the town, and that insufficient food and clothing had a great deal to do with the increase.

Notification of Whooping-cough and Measles at Newcastle.

An important discussion took place last week at a special meeting of the Newcastle Sanitary Committee as to the notification of whooping-cough and measles. Dr. Armstrong, the city health officer, reported that since the notification of scarlet fever there had been a decided decrease in the number of cases. Measles had now assumed a serious aspect, no fewer than ninety-five deaths having taken place during the last quarter alone from this disease. It was maintained by some members of the committee that the improvement with respect to scarlet fever was due more to the action of the Sanitary Committee than to notification. Others were rather inclined to think that notification had done a good deal to bring the medical officer and his staff into close connexion with the people; and this, with the instructions issued regarding isolation and other matters of importance, had proved of immense benefit to the people themselves. This important discussion was adjourned for a fortnight. Meantime there is a feeling growing in the profession that measles and whooping-cough might well be included in the schedule of infectious diseases, seeing how rapidly these affections are disseminated by school children. Before I leave this subject, as showing the exceptionally high death-rate of late prevailing in Newcastle, I may say that at a late meeting of the Elswick Burial Board it was stated that as regards the Elswick cemetery, the interments in December (235) were fifty in excess of any previous month since the opening of the cemetery in 1857.

Carlisle: Death of Dr. D. Scott Carlyle.

I regret to record the death of Dr. D. S. Carlyle, which took place on the 4th inst. at Warwick House, near Carlisle, in his sixty-fifth year. Dr. Carlyle was a mycologist of repute and a devoted collector of fungi of all descriptions, and up to the time of his last illness he was constantly sending specimens to Kew, many of them rare, and some of them occasionally new to Cumberland and to Great Britain. He lectured frequently on his favourite theme at meetings of the Carlisle Microscopical Society and the Carlisle Scientific and Naturalists' Field Club. His cabinets were filled with specimens, and it has been suggested that a place should be reserved for them in the new Carlisle Museum. Dr. Carlyle was physician to the Carlisle Fever Hospital and to the Dispensary, and during the many years he lived in the city he had a large practice, and was a great favourite with the rural population in the neighbourhood.

With regard to the sad accident to Mr. Dunlop, surgeon, of Leamside, noted last week in this correspondence, I am happy to say that the reports as to his condition continue favourable.

Newcastle-on-Tyne, Jan. 12th.

EPSOM COLLEGE.—F. G. Thomson, a pupil in the sixth form of the college, has gained a scholarship of £40 for Natural Science at Sidney Sussex, Cambridge.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Medico-Chirurgical Society of Edinburgh.

A SPECIAL meeting of this Society was held on Wednesday of last week, and was occupied by a demonstration from Mr. Harold Stiles, with limelight views, of the changes in the mammary gland in cancer with special reference to operative procedure. The first point he took up was that the gland was larger and extended over a greater area than was taught in the books, extending both higher and further into the axilla than was usually described. He had introduced a simple and practical test which indicated whether all the gland was removed or not. This was by placing the removed gland in a 5 per cent. solution of nitric acid; this solution had the effect of giving the glandular epithelium a yellow colour, and if this showed on the cut surface it indicated that the gland had been cut across and not removed at that part. He showed a number of slides illustrating this point, the glands being from operation cases. As to the mode of extension of cancer in the breast, he held wholly to the view that it took place by the lymphatics. He insisted on the importance of removing the whole gland and leaving no remnant of it behind. Passing from the mamma itself, he then dealt with the structure of parts in the axilla, and showed that they might be so slightly affected that no indication of involvement was present save by microscopic examination, and he therefore argued that in all cases the axilla ought to be cleared.

Edinburgh Association for the Reform of Medical Education.

A statement prepared by this Association for presentation to the Universities Commission has appeared in the local newspapers, and has been followed by a number of letters bearing upon the points raised by the statement, and most of these advocate even more forcibly than the statement itself the necessity for reform. The general tone is one of thorough dissatisfaction, and there promises to be even more plain speaking. The professoriate feel acutely the rebellion against their actions and judgment, for they are not accustomed to the strictures and criticisms now being hurled against methods and systems which have in the past been so remunerative, and with which they were abundantly satisfied.

Glasgow Medico-Chirurgical Society and Tuberculosis.

A memorial has been drawn up by the Medico-Chirurgical Society of Glasgow for presentation to the Police Commissioners, on the subject of the danger existing from the infectious nature of consumption or tuberculosis in man. The memorialists urge the necessity of preventing the sale of tuberculous meat, and dwell upon the danger arising from the use of milk given by cows kept in town byres. A rigid cleansing and disinfecting of byres and condemnation of carcases of animals known to be tuberculous are recommended. The Society suggest that the authorities should make widely known the fact that consumption is infectious, and suggest that the sanitary staff should extend its disinfecting operations to the houses of those suffering from the disease.

Health of Edinburgh.

The mortality last week was 114, making the death-rate 22 per 1000. Diseases of the chest accounted for 46 deaths, and zymotic diseases for 3. The intimations for the week were: Typhus fever, 4; typhoid fever, 4; diphtheria, 2; scarlatina, 16; and measles, 23.

Jan. 11th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The late J. H. Wharton, F.R.C.S.I., &c.

AT a meeting of the Standing Committee of the Meath Hospital, held last Monday, the following resolution was unanimously adopted: "That this committee, at their first meeting held after the lamented decease of their esteemed friend and colleague, Mr. James H. Wharton, desire to express their sincere sympathy with his family in their sore bereavement, and their unfeigned sorrow at the great loss which they have sustained. They also desire to record their grateful appreciation of the great interest which Mr. Wharton took in this institution, and the invaluable services which he rendered to it during a period of nearly forty years."

The Influenza Epidemic.

The epidemic shows no signs of abating, but on the contrary has increased in Dublin and various parts of Ireland. In Newry the cases have been exceedingly numerous, and churches have been closed because the officiating ministers were victims of the epidemic. Influenza is spreading rapidly throughout East Tyrone; it is very prevalent in Cookstown, and is on the increase in Dungannon, Coalisland, Coogh, and Pomeroy. A large number of deaths have occurred in these towns, and a large percentage of the inhabitants in the rural districts are affected. Mr. Z. Johnson, F.R.C.S.I., of Kilkenny, one of the oldest medical practitioners in this county, is seriously ill with influenza.

The Vartry Water-supply.

A special meeting of the Dublin Corporation was held on Monday to consider the allegations made against the water-supply of that city. Several members had visited Roundwood, and examined every drain and sewer in the village, and they asserted that there was no contamination entering the Vartry reservoir from any service. If any contamination did leave the village it would pass through 200 yards of a stream before it could get to the Vartry supply. Five samples of the water, all taken before the water entered the reservoir, were examined by Sir C. Cameron, medical officer of health and city analyst, who made careful observations of the surroundings of the reservoir. The filtered Vartry water contained no suspended matters, and included a few unimportant micro organisms. It contained per imperial gallon albuminoid ammonia 0·006 grain, and saline ammonia 0·001 grain. The liquid from the upper part of the "Roundwood Drain" was slightly yellow, contained various micro-organisms, and had a slightly unpleasant odour; an imperial gallon yielded 0·027 grain of albuminoid ammonia and 0·012 grain of free ammonia. A specimen taken at the end of the drain contained per gallon 0·024 grain of albuminoid ammonia and 0·008 grain of free ammonia, while a specimen taken from the upper end of the drain yielded 0·013 grain of albuminoid ammonia and 0·011 grain of free ammonia. These facts and analyses are reassuring as to the quality of the water which supplies the city of Dublin, and it is to be hoped that we have heard the last of the damaging reports which of late have been circulated as to the alleged impurity of the Vartry.

Proposed Hospital for Consumption.

It is proposed to establish a National Hospital for Consumption for Ireland, and a provisional committee composed of influential members of the community has been formed. The matter is one of considerable importance, and I shall have something further to say about it in a future letter.

The Progress of Belfast.

The city of Belfast continues to increase by leaps and bounds, and its progress during the past year is quite remarkable, and altogether beyond that of any other town in Ireland. During the last twelve months 2215 new houses have been built in Belfast, and ninety new streets have come into existence. The buildings erected in 1891 exceed those of 1890 by 221, or about 9½ per cent. Taking the total buildings erected during the past thirty years, the average number per annum has been 1300, so that 1891 is about 71 per cent. above the average. The total valuation of Belfast in January, 1862, was £279,057; it is now £717,077. The rated wealth has therefore more than doubled. This increase has annually been about £14,600. This year that increase has nearly doubled. Of no other towns in Ireland—and it is doubtful if indeed of any in England or Scotland—can it be said that during the past thirty years the valuation has all but trebled, as in Belfast. I regret to say that the report presented by the medical officer of health at the meeting of the City Council on Jan. 1st shows that the health of Belfast is far from satisfactory. In the four weeks ending Dec. 19th there were 596 births and 813 deaths—that is, the death-rate so far exceeded the number of births that there was an actual decrease in the number of the population of 217. The death-rate was 41·4 per 1000; while for the corresponding four weeks in 1890 the mortality was only 25·3. The death-rate from diseases of the respiratory organs has been more than doubled by the influenza epidemic. It is now generally believed the maximum virulence of this disease has been

Digitized by Google

passed. It is a curious fact that typhus fever, which had almost died out, has again appeared, and is not confined to any particular district. The medical officer of health (Dr. Whitaker) says he cannot assign any cause for its reappearance. At the present time a great many horses are suffering from influenza. So much is this the case that the tram-service in consequence has been to a certain extent curtailed; and several other companies, employing large numbers of horses, have been much inconvenienced by the illness of their horses. This malady in horses is known as "pink-eye"; and although practically the whole stud of the Tramway Company (800 horses) has been infected, the rate of mortality has been very low—only 1½ per cent.

The Lord Chancellor has appointed Dr. Magee Finny, President of the Royal College of Physicians, to be Medical Visitor in Lunacy, in the place of the late Mr. Wharton.

Mr. Digby Ffrench, F.R.C.S.I., died on the 10th inst. at his residence, Clarinda Park, Kingstown, at the ripe age of eighty-five years. Mr. Ffrench formerly practised at Monivea, co. Galway, but retired many years since. Mr. Ffrench leaves three sons, all members of the profession.

Mr. Dunne, joint secretary of the Royal University of Ireland, died on Sunday last, after a short illness.

Jan. 12th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Recent Census in France.

THE last census gives the total population as 38 343,192, while that of the previous census was given as 38,218,903, thus showing an augmentation of the total population of the French Republic of 124,289 since 1886. During the period between 1881 and 1886—1881 being the epoch of the previous census—the increase was considerably greater—viz., 545,855—and this is noteworthy especially when it is remembered that the last census embraced a period which was longer by five months and a half than the period of the census before. The gravity of this decrease in the eyes of patriotic Frenchmen is not denied, but some plausible explanations are put forward by the compilers of statistics in the department of the Ministry of Commerce. It is submitted that in a certain measure the decrease may be largely accounted for by certain epidemics which visited the country in 1890, and by the crisis which affected the births thirty-six years ago, and which was considerably aggravated by the high mortality in 1854 and 1855. Moreover, it is further pleaded that as another factor in the causation of the diminution must be added the losses sustained in 1870-71. The men who died at this period were mostly able-bodied and young, and it is not unreasonably held that their disappearance in thousands would now be felt to influence the census in a downward direction. But however this may be, the Minister of the Interior is obliged to admit with regret that the population of "la Patrie" appears to be at a standstill. Others go further, and predict that the present quantity, although still a *plus* one, is destined ere long to become a minus one.

Massage in Headache.

M. Norstrom records twenty observations of cases of headache, which had proved refractory to all manner of treatment, successfully treated by massage. The patients were the subjects, not of migraine in the ordinary sense of the term, but of acute pain returning in paroxysms. M. Norstrom further records that he found in these cases numerous small indurations—which were generally overlooked—in the substance of the muscles of the neck. These indurations were very sensitive to the touch; he considers them as rheumatic in character, and believes they are the chief factor in the cause of the kind of headache under consideration. They are generally to be met with on the sterno-mastoid and trapezius, sometimes in the scalp itself. He believes that it is by the pressure they exert on the nerve filaments that they induce headache. For such cases he speaks highly of massage properly carried out. This should be gentle and long continued.

Laryngismus Stridulus treated by forcibly dilating the Larynx.

At a recent meeting of the Société de Thérapeutique M Constantin Paul read notes of a case of laryngismus stridulus which was successfully treated as follows:—The patient was a child of fourteen months old, which had for three nights in succession such severe attacks of laryngismus stridulus that its life was in danger and tracheotomy was thought to be necessary. This operation being, however, often fatal in children under two years, M. Paul requested his house physician to practise forcible dilatation of the larynx should another paroxysm supervene. The occasion arising, M. Malbec, the house physician, did forcibly dilate the child's larynx by means of a long polypus forceps, with the result that the attack was averted, and has not, moreover, since then recurred. M. Paul therefore recommends the manœuvre for trial at the hands of others.

Association of Foreign Physicians.

Another association of foreign medical men practising in France, on broader lines than the one already in existence, and which for various reasons cannot be called a brilliant success, has just been started. The number of foreigners practising in this country is difficult to estimate, but it is believed that Paris alone can boast of no fewer than 250, more than a tenth of the total number of Parisian practitioners.

Paris, Jan. 13th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Influenza Bacillus.

THE discovery of the germ of influenza was publicly announced on the 7th inst. in the lecture hall of Koch's Institute for Infectious Diseases. The discovery was made by two Berlin investigators, who worked independently and at different places: first by Dr. Richard Pfeiffer, head of the scientific department of the above-mentioned Institute; and then, a short time later, by Dr. Canon of the Moabit Hospital. The identity of Canon's bacillus with Pfeiffer's has been certified by Koch. Dr. Pfeiffer spoke first. When the influenza broke out again last November, Koch had entrusted him with the task of studying the disease, with a view to ascertaining whether it was caused by a micro-organism. Favoured by fortunate circumstances, he was able to solve the problem in a fortnight. He examined the sputum of influenza patients, first sterilising and cleansing it by Koch's methods, and then treating it with Ziehl's solution or Loeffler's hot methylene blue. A large number of micro-organisms then became visible under the microscope, and it soon appeared that they were mostly of the same kind. This was always the case with the sputum of patients suffering from influenza alone. When the disease was accompanied by other pulmonary disorders other bacteria were also visible in the sputum. The sputum of a large number of patients suffering from pulmonary and other diseases, but not from influenza, was examined, but no micro-organism possessing the qualities which characterised that found by Pfeiffer in influenza was found. It was intelligible that this bacillus had so long escaped detection, for it was far smaller than any micro-organism hitherto known, and the circumstance that its two extremities stained more intensely than the intervening parts gave them a striking resemblance to diplococci and streptococci. The bacilli were found copiously in the mucus and cells of the sputum; in the latter often degenerated. One of their characters was immobility. Dr. Pfeiffer's next task was to cultivate the bacillus in pure cultures, and here a new explanation of the lateness of its detection came to light. The colonies were so small that they could easily be overlooked. At first they were visible only under the magnifying glass. Glycerine agar had proved the best nutritive medium. The most characteristic thing about this bacillus was that the colonies did not flow together, but remained separate. The results of the examination of the sputum had been entirely confirmed by post-mortem examinations made by Pfeiffer in the bodies of six patients who had died of influenza. In all the influenza bacilli were found in the parts affected. He then tried to produce influenza in monkeys, rabbits, guinea-pigs, rats, pigeons, and mice by inoculating the bacilli, but had succeeded as yet only with monkeys and rabbits. In conclusion, Dr. Pfeiffer referred to the prophylactic measures indicated by his discovery, laying special stress on the importance of carefully removing the sputum of influenza patients. After Dr. Kitasato, who had assisted Dr. Pfeiffer in his researches, had said a few words, Dr. Canon reported on his independent discovery of the bacillus. He examined under the micro-

Digitized by Google

scope blood taken from influenza patients during fever, and found organisms hitherto unknown, which attracted special attention by the circumstances that they were found only in the case of feverish influenza patients, and disappeared from the blood as soon as recovery took place. Their number varied considerably. An examination of his discovery by Koch and Pfeiffer showed that his bacilli were the same as Pfeiffer's. Dr. Canon is of opinion that the detection of this bacillus in the blood of a feverish patient completely suffices to justify the diagnosis of influenza. It is interesting to note that Dr. Pfeiffer saw and even photographed the bacilli now recognised as the germs of influenza two years ago. Dr. Kirchner of Hanover believed that he had discovered the germ of influenza then. It was not so; but the genuine bacteria were in the photographs made for him by Pfeiffer. Their importance was not even guessed at that time.

Berlin, Dec. 12th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Drainage of Cairo.

IT will be remembered that the Egyptian Government employed Mr. Baldwin Latham two years ago to elaborate a scheme for the drainage of the capital, for which the fee of 800 guineas was paid. The native Ministry at that time was opposed to reform, and no further step could be taken until last spring, when the more enlightened Prime Minister of to-day came into power. Egypt begged the six great European Powers, without whose consent she is powerless to effect any new expenditure of her own savings, to authorise her to set apart half the octroi duties of Cairo to pay for the city's drainage scheme. France, pursuing her usual policy in this country, refused her consent; but has now imposed the following conditions which have been forced on unwilling Egypt. Any projects for the sewerage of Cairo must be submitted before Jan. 31st, 1892, to a committee of three engineers, English, French, and German, who are to report upon them to Egypt. If these three are not unanimous their difference is to be submitted to a fourth engineer, as arbitrator. The arbitrator may be chosen by them, provided he is not an Egyptian employé, and provided he is not of the nationality of any of the three. If they reject all the submitted schemes, they are empowered to prepare their own project; if, however, they select one of the proffered plans, its originator is to receive £200. The terms have been already advertised in three English journals, and are a ludicrous and ingenious device on the part of the French Government to delay a much-longed-for reform, the only objection to which is that it has been proposed by Englishmen. The £200 prize is absurdly small, and will hardly tempt English sanitary engineers of repute to compete; but, on the other hand, the various plans for dealing with Cairo sewerage which have been already brought before and rejected by the Egyptian Government will all be represented. The names of the three judges are not yet known, but it is said that France will nominate the chief engineer of the Paris drainage works.

The Tourist Season.

In spite of the absence of all drains, Cairo is exceptionally healthy, and the other towns of Egypt have a comparatively low rate of mortality. The weather has been more than usually bright and sunny since the beginning of November, though for two hours on the morning of Dec. 7th we had not only rain, but passing hail and thunder. Exactly half an inch of rain fell on this occasion, and owing to the absence of all street drains some of the lower parts of the town were flooded for two or three days, requiring the service of water-carts to empty the pools. A new market has lately been erected by the Wakfs under the supervision of the Public Works Department, a reform which has been greatly needed for years. Some energetic attempts on the part of sanitary and veterinary employés to examine the meat sold by European butchers were met with such determined opposition by French and Greek salesmen that the practice had to be abandoned. A native butcher selling unsound meat can be suitably punished, but the European, protected by his consul, cannot even be fined. Some cooked pork bought from a European last week was found to contain the Cysticercus cellulosæ, and this is, I believe, the first time it has been reported in Egypt.

Quarantine Congress at Venice.

The three delegates from Egypt have left for Venice. They are Boutros Pacha, the Coptic Under-Secretary of Justice, Mr. Miéville, the English President of the Alexandria Quarantine Board, and Dr. Mahmoud Pacha Sidki, the Egyptian Vice-Director of the Sanitary Department. Egypt's cause may possibly be further aided by one of the English representatives, Dr. Mackie of Alexandria. The Congress meets on the invitation of Austria, and will probably resolve itself into a duel between French and English, upon the vexed question of suspected ships passing through the Suez Canal without delay. The members for France are a very powerful trio, M. Camille Barrère, who was French Minister in Egypt some five years ago, Dr. Brouardel, who has already officiated at many congresses, and Dr. Pronst, the eminent professor of hygiene. The constitution of the motley quarantine board at Alexandria is to be discussed, and it is to be hoped that some of its farcical proceedings will be put a stop to. A new tariff of taxation is to be proposed, raising the present fees almost three times what they now are. This will have the effect of enriching the finances of the Board and of relieving Egypt, while the Board itself will probably become even more international than it is at present. I may mention here that an English gentleman who reached Alexandria at the end of October from Syria was kept for eight days in quarantine there, for fear of cholera. He was then in the third week of a typical attack of enteric fever, which was not discovered by the doctor and other officials who visited him every day. He and his friends were afraid to declare the nature of his illness lest the whole number of passengers should be suspected of being cholera-stricken, and their imprisonment extended indefinitely. An inspection system which cannot detect enteric fever is not likely to be very efficacious against cholera. On the other hand, quarantine regulations against unclean pilgrims returning from Mecca to Egypt are, as the only method of enforcing cleanliness, of some value.

Cairo, Dec. 29th, 1891.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

MR. F. C. BATCHELOR has published a very interesting paper in the *New Zealand Medical Journal* on "A Year's Work in Abdominal Surgery." The paper was originally read before the Otago Branch of the Association at the Dunedin Hospital. During this period Mr. Batchelor's connexion with the hospital has been practically severed, and the paper in its present form is the result mainly of private cases. Mr. Batchelor opened the abdominal cavity in twenty-nine instances. They may be thus classified: Ovariotomies, 7; Tait's operation, 6; Hegar's, 1; Battey's, 5; hysterectomies—abdominal, 2; vaginal, 1; laparotomy (for various reasons), 7. These operations have been most successfully performed, for they have been conducted without a single fatality, the patients making, according to the detailed table which accompanies the paper, excellent and rapid recoveries. Under the heading of the ovariotomy operations Mr. Batchelor remarks that in the whole series the highest registered temperature was 100·4° on the third day. Tait's operation was performed six times. In every case the original condition of the patient was found to be so serious that the operation was considered absolutely necessary to save life or to render it bearable, and each case had previously undergone prolonged medical treatment without relief. As Mr. Batchelor very justly remarks, it is the operation for the removal of the ovaries, normal or abnormal, to induce the climacteric that is so open to debate. It is in this class of case that the enthusiastic gynæcologist in all parts of the world is so apt to overstep the bounds of prudence. The symptoms necessitating operation in Mr. Batchelor's opinion are described in detail, and every case seems to have been very carefully weighed. The result of these six cases shows a cure in one instance, no apparent advantage gained in one case, and improvement more or less in the remaining four. Mr. Batchelor remarks that during the past year he has taken no new or extraordinary antiseptic precautions, but has simply, as heretofore, endeavoured to carry out strict cleanliness in all surgical proceedings, which it would be impossible to do in the wards of a general hospital in an admittedly insanitary condition.

St. John Ambulance Association.

This Association has a flourishing branch in Christchurch. Mr. Hacon is to be congratulated on the results of his efforts to promote the Association, for it has now been doing excellent work for six years past. Branches, too, have been started in the principal towns of the colony, and much public benefit must accrue. There is, however, urgent need for good nurses throughout the colony, and medical men in practice experience great difficulty in obtaining really good nurses. A "Nurses' Directory" has been started in Auckland, and other parts of the colony would do well to follow the lead thus given. Good nurses receive good pay in this colony, and they are sure of obtaining employment; for anyone who has once gained the reputation of being an efficient nurse is eagerly sought after. Nurses coming to this colony from England I should strongly advise to go through the course of training such as is obtained at Queen Charlotte's Hospital, London. Nurses holding these certificates are not too readily found here.

Wanganui.

Tourists will be glad to learn that the Wanganui river, which has gained such a reputation for the beauty of its scenery, is now provided with a new steamer specially built for the tourist demands. The steamer is owned by Mr. Hamrick, and is subsidised by the Government. It is believed that she will do the journey to Pipiriki easily in the day, thus meeting a want which has long been felt. She has just made her initial trip, doing twelve miles an hour, and gave every satisfaction. She was built by Messrs. Yarrow and Co. of Poplar, and is so constructed that she draws only sixteen inches of water, and can be depended on to run regularly to Pipiriki, to which place and back to Wanganui makes 120 miles of river travelling. She runs in connexion with Messrs. Cook and Sons, and this enables tourists to readily visit the hot lakes from the west coast or *vice versâ*.

Obituary.

PROFESSOR BERKELEY HILL, F.R.C.S.

IT is with great regret that we record the death of Professor Berkeley Hill, which occurred on Jan. 7th at his residence in Wimpole-street. Mr. Hill's death is a great loss to the profession, and those who knew him best will mourn him most. Matthew Berkeley Hill, the youngest son of Matthew Davenport Hill, the first Recorder of Birmingham, was born on June 12th, 1834, at the Vale of Health, Hampstead. Berkeley Hill was educated at University College School, London, under Mr. Key, and also at Bruce Castle, Tottenham, the family school, which, at the time he was a scholar there, had passed from the management of his uncle, the late Sir Rowland Hill, into the hands of his (Sir Rowland's) brother, Arthur Hill. On his father's removal to the neighbourhood of Bristol, in 1851, Berkeley Hill took up the study of chemistry under Mr. Thornton Herapath, intending to take up the profession of analytical chemist; but eventually turned his attention to the study of surgery. He studied medicine at University College, with which he was connected during the whole remaining period of his life. Having taken the degree of M.B. and the Fellowship of the Royal College of Surgeons, and having passed a year as house surgeon in the Ormond-street Children's Hospital, he went abroad in 1861 for further study at Berlin (where he made the friendship of Virchow), Vienna, and Paris. He also visited several of the Italian hospitals, especially the one at Naples, which he described as being then much behindhand.

At the end of 1862 he commenced practice in Weymouth-street, and shortly after was appointed assistant surgeon to University College Hospital. In the spring of 1863 he "sat" for Sir Henry Thompson, who had been called to Brussels to operate upon the late King of the Belgians. In 1864, 1866, and 1869 he took a great part in promoting the passing of the various measures relating to contagious diseases. In 1870 the storm began which ended in their temporary abrogation. Berkeley Hill, as secretary to the Society (in conjunction with Mr. Curgenven) for the extension of these Acts to the civil population, spared neither strength, time, professional prospects, nor anything else in the cause. The abuse that was poured on him, in common with every one who tried to diminish human suffering, especially of the innocent, by means of this legislation; the falsehood which assailed him on every side, never caused him for a moment to swerve from what he knew to be right. The labour was enormous, but was cheerfully undertaken and persevered in for years. At one time he debated whether he should not devote himself entirely to this work, and relinquish practice altogether. In the autumn of 1870 he went to the districts devastated by the Franco-Prussian War to distribute the stores of the Red Cross Society, of which Colonel Lloyd Lindsay, now Lord Wantage, was the active chief. Berkeley Hill was elected on the Council of the College of Surgeons in 1884, and in 1886 was chosen one of the examiners for the College, and in 1891 Vice-President of the Council. Both in face and in character he greatly resembled his uncle, Sir Rowland Hill, especially in indomitable perseverance, in fertility of resource, and in the ability to grasp the salient points of every subject. In 1868 he married the youngest daughter of the late Sir Thomas Howell, of the War Office, by whom he had six children, five of whom survive him. Throughout his last illness he was attended by devoted professional friends, among whom may be mentioned Dr. Barlow, Dr. Eustace Smith, Mr. Marcus Beck, Mr. W. Meredith, and Mr. Charles Stonham, whose care and skill were employed to save him from all possible suffering.

Like his father and his uncle, Berkeley Hill was really public-spirited—ready, that is, to sacrifice energy, time, and money without a thought of self-seeking or the gratification of personal vanity. This was abundantly recognised by his colleagues at University College, who elected him Dean of the Faculty of Medicine for three years in succession, a term of office which is unprecedented, and who selected him to be the first representative of the Faculty upon the Council of the College so soon as the much-needed reform of admitting professors to the Council Board had been conceded. The improvement of the discipline of the College, the proposed rebuilding of the Hospital, and the establishment of a teaching university in London were among the questions which Berkeley Hill had much at heart, and in the furtherance of which he took a large part.

It was the recognition of his unselfish public spiritedness, in addition to his surgical and scientific eminence, which made doubly certain his election to the Council of the College of Surgeons in 1884. As a councillor or committeeman he was invaluable. His attendance could always be relied upon, and his clear-headedness, attention to business, and impartiality in decisions were certain. Another strong characteristic was tenacity of purpose. Having put his hand to the plough, Berkeley Hill was the last man to look back. His noble attitude with regard to the Contagious Diseases Acts was the best evidence of this, but it was also abundantly shown in many minor actions. His enthusiasm was easily aroused in what he regarded as a righteous cause, and although his decisions were at times impetuously taken, once arrived at he was not easily turned from them. When it has been said that a man was public-spirited and tenacious of his purpose, it is almost unnecessary to allude to his honesty; and yet in this instance it is well to do so, for Berkeley Hill's honesty was absolute. He was incapable of deception by look, word, or deed; and although his practice was a large one, and he retained the confidence of his patients in a manner quite unusual, it is well to place on record that his success was due to his sterling qualities as a practitioner, and in no degree to the arts and little artifices known as professional "side," for which, in all its forms, Berkeley Hill had a good-humoured contempt. In concluding this review of the moral qualities of the deceased, his kindliness and generosity must hold the place of honour. How many students and professional friends have experienced his goodness and generosity when stricken by illness or misfortune it would be hard to say. Though rather impassive on the surface, he had nevertheless a keenly sensitive nature, apt to be stirred by generous emotions, which evoked in him the neighbourly actions of a true Christian and the hospitable instincts of a thorough Englishman. No greater proof of this could be given than in the tokens of personal regard and of genuine grief shown in the wreaths which at the funeral lay on the coffin. Some of them were from men who, young and careless, were in danger of wrecking their life had not the wise counsel and the timely help of the elder man arrested and turned them back again into the path he himself pursued. The pleasure he felt when such a young man gave evidence that the exertion had not been in vain was keen

Digitized by Google

indeed; but the secret had been so strictly kept that letters of gratitude, written by those who received this friendly help, only now reveal (even to his nearest relatives) what he had done. Of his intellectual endowments, his writings and his high professional status are the best evidence. That Mr. Berkeley Hill was in the very front rank of European syphilographers goes without saying, for his works are read and appreciated wherever surgery is studied. Not only is his great work, "Syphilis and Local Contagious Disorders," prepared with characteristic thoroughness and great clinical experience, accepted as a sound and exhaustive text-book, but it will be acknowledged that Berkeley Hill's enterprise and industry have done much to advance the surgery of the genito-urinary system in this country. The question of internal urethrotomy received his early thought, and not only did he call attention to the work of Otis in this direction, but he perfected methods and devised an operation and instrument of his own. In 1888 he was appointed Hunterian Professor of Surgery and Pathology at the College of Surgeons, when he chose Endoscopy as his subject—a subject which he was largely instrumental in bringing to the notice of the profession in this country.

In 1881 he communicated a case of the removal of a tumour from the female bladder by means of an écraseur through the dilated urethra. At this time only twenty-eight similar cases had been recorded. It must be borne in mind that Berkeley Hill was no mere specialist. His education had been liberal and broad. His knowledge of the classical and European languages was exceptionally good. He had travelled extensively throughout Europe, and had studied in Vienna, Paris, and Berlin. Having passed an honourable career as a student, he became demonstrator of anatomy, and during the time that he was acting as assistant surgeon at University College he produced a successful work on Bandaging, and made many contributions to general surgery. After his appointment to the Lock Hospital his attention became more and more restricted to his special subject; but his specialism was due entirely to the trust reposed in him by the profession and the eagerness with which his opinion was sought by those who appreciated his scientific acumen, clinical experience, carefulness, and honesty.

JAMES CHRISTIE, M.A., M.D.

DR. JAMES CHRISTIE was born at Strathaven in May, 1829. Trained and educated at the Glasgow University, he was ordained in 1856 as a dissenting minister, but a weakness in his throat led to his retirement from that field of labour, and in 1860 he obtained his degree of M.D. from the University of Glasgow. He was a general practitioner, not in the ordinary sense of the term, but in the widest sense—a man of extended knowledge, of erudite mind, and a painstaking and earnest seeker after truth. His views on the subject of medical education were very pronounced, and much in advance of his time. His residence as assistant physician at Gartnavel gave him an insight into psychological medicine which few general practitioners could hope to equal, and few alienists to surpass. He continued to take an interest in cases of insanity until the end of his career. He held the appointment of physician to the Sultan of Zanzibar, where he brought his acute observation and literary powers into action, with the result that on his return to Glasgow in 1875 he produced a much-esteemed book entitled "Cholera Epidemics in East Africa from 1821 till 1872." He wrote also on other tropical diseases, and on some of the great epidemics. A joint production of his with H. A. Fraser and Bishop Tozer appeared in London in 1871 on "The East African Slave Trade and the Measures proposed for its Abolition." While at Zanzibar he became acquainted with Dr. Livingstone, and it is said that Dr. Christie was the last white man the great traveller saw on his departure for his final exploration. The servant who embalmed Livingstone's body was one who had worked under Dr. Christie, and had probably acquired technical knowledge with him sufficient to enable him to do so. In 1876 he was appointed one of the surgeons to the out-patient department of the Glasgow Western Infirmary, being transferred a few years ago to the post of assistant physician in that institution. His special aptitude lay in the direction of literature. He wrote for the "Globe Encyclopædia"; he edited the *Sanitary Journal* almost from its commencement, a congenial work, and consequently carried out in a style worthy of a master in the science of sanitation. Dr. Christie was a corresponding member of the Medical and Physical Society of Bombay; an associate of the Society of Hygiene of France; secretary of the Epidemological Society of London for the district of the Indian Ocean and East Africa; and a number of various other learned societies.

His special knowledge of tropical diseases led to his being asked to write the articles on some of these subjects in Dr. M'Call Anderson's "Treatise on Skin Diseases" (1887). Another little production of his pen, on which he had expended much time, was "Epidemics of Dengue Fever: their Diffusion and Etiology." This appeared in the *Glasgow Medical Journal* in 1881. It has a special interest at the present time, when various authorities allege the relationship or the identity of our prevalent influenza with this peculiar disease. His connexion with Anderson's College, in which his interest was deep, began with his appointment to the chair of public health in that institution in the year 1878. In 1884 he was appointed to the chair of Physiology in that College. In that capacity he was a teacher of the few rather than of the many. He invariably kept up the attention of diligent students who were really anxious to learn, not by the aid of happy illustrations and appropriate anecdotes, but by the quantity and quality of the instruction which he conveyed. For those of an inferior class his lectures were almost too good, and delivered almost in too classical a style. Their literary merits were extremely high, and many note books are in existence from which his lectures might be printed almost without revision. Hampered as he was in many ways, he spared no pains and no personal expense to advance and attract the dilatory students. His sympathy with the class of students for which Anderson's College primarily existed was unbounded, and his generosity great almost to a fault. "I have," he said to the writer of this obituary notice, "very great sympathy with those students who have brains and but little money to enable them to advance. "But," he added confidingly and encouragingly, "if there are any I pity more it is those who have money and but little brains." He was beloved by his pupils and his colleagues for his unfailing kindness. His utterances at all times were listened to with the attention and the respect which a cultured mind and a gentlemanly bearing command. His death will be felt to be a distinct loss to the medical profession, and more especially to Anderson's College, in which, if not the greatest, he was certainly not the least, ornament. He was one of those

> "Whose good is quick and mighty, far and near,
> So that fruits follow it."

DR. G. D'ANCONA.

EGYPT was the principal scene of this eminent physician's life work, and, particularly at Cairo, he was the promoter of much that has since fructified to advantage in the teaching and the practice of medicine. A Tuscan by birth, Giacomo D'Ancona studied at Florence, his native city; thence he repaired to Pisa for systematic training in medicine and surgery, finally returning to Florence for the completion of his curriculum, with a view to graduation. After taking his degree, which he did with much distinction, having, among other honours, gained the Tacchini prize, he went to Paris, and there devoted himself sedulously to clinical observation and treatment. His reputation as an accomplished physician was now established, and he was chosen to fill the chair of pathology in the Medico-Chirurgical School, which, at the instance of Abbas Pasha, was to have been founded in Cairo, under the presidency of Professor Ranzi of Pisa. The school never actually took shape; but Dr. D'Ancona remained in Egypt for many years, promoting medical education in every way open to him, and filling the post of body-physician to the son of the Khedive. It was at this time that he made his well-known researches into the eye diseases peculiar to Egypt; but a call to Paris prevented his completing the publication he had begun on that theme. In the French capital he soon rose to a high position in the Italian colony, and also in general society, recommended as he was, not only by professional skill, but by quite a diplomatic finish of manner and address. He assisted the celebrated Dr. De Mars in his consultations on eye diseases and in the more delicate operations; while he had a *clientèle* of his own, scarcely less numerous, in other departments of practice. True to the interest he always

Digitized by Google

took in the profession, he represented Italy at many Congresses, medical and surgical, and superintended the Italian sections of not a few expositions of a scientific kind. For these and similar services he received the Orders of St. Maurice and of the Crown of Italy. Many benevolent institutions will miss his ever-ready sympathy and help, not least among them the "Società Italiana di Beneficenza" at Paris. His death took place quite suddenly at Pisa on the 8th inst., in his sixty-sixth year. He had returned in his usual health from Florence, where he had been the guest of his brother, the Senator D'Ancona, when he succumbed to an apoplectic seizure.

ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary comitia of the College took place on the 14th inst., the President, Sir Andrew Clark, Bart., in the chair. At the commencement of the proceedings the President alluded in feeling terms to the public calamity which had just fallen on the nation in the death of H.R.H. the Duke of Clarence, and, at his suggestion, the College, on the motion of Sir Joseph Fayrer, seconded by Dr. G. Harley, resolved to transmit an address of sympathy and condolence to Her Majesty the Queen, and their Royal Highnesses the Prince and Princess of Wales.

The President nominated Dr. Gee to be Bradshaw Lecturer for the present year.

Letters were read from the Royal College of Surgeons, the Registrar of the Branch Medical Council for Ireland, and the General Medical Council.

Permission was granted to Dr. S. Martin to deliver the Goulstonian lectures in the Theatre at the Examination Hall.

A report from the Committee of Delegates of the two Royal Colleges on the Scheme for a Five Years' Curriculum and the revised Regulations for Examinations were adopted, on the motion of Sir R. Quain, seconded by Dr. N. Moore. The President eulogised the labours of the Committee, which had been thus brought to a successful close.

The opinions of the Attorney-General and Sir Arthur Watson, Bart., Q.C., on the question of the non-registration of the licence and membership of the College as complete qualifications were read; and other questions in relation to the same subject were reported to the College by the registrar. The recommendation of the Committee of Management that the course of operative surgery given by Mr. Thomas Cooke be recognised for the ensuing year was adopted.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council of the above College, held on Thursday, the 14th inst., the minutes of the ordinary Council on Dec. 10th were read and confirmed.

On the announcement of the death of the Duke of Clarence and Avondale, as in the proceedings of the Royal College of Physicians, a vote of sympathy and condolence with Her Majesty and the Prince and Princess of Wales was unanimously agreed to.

The Secretary reported the death on the 29th ult. of Mr. John Wood, F.R.S., past Vice-President, member of Council, and member of the Court of Examiners of the College. The Secretary also reported the death on the 7th inst. of Mr. Matthew Berkeley Hill, Junior Vice-President, member of Council, and member of the Court of Examiners of the College. In each instance the Council unanimously passed a vote of condolence with the family of the deceased.

The vacancy in the Council caused by the death of Mr. Hill will be filled in July next, at the annual election. A Vice-President for the remaining period of the collegiate year will be elected at the next meeting of the Council in February, and the vacancy in the Court of Examiners will also be filled up at that meeting.

It was agreed that, as recommended by the Museum Committee, Mr. R. H. Burne, B.A. Oxford, be appointed anatomical assistant in the museum, at a salary of £150 per annum, subject to annual re-election at the Quarterly Council in July.

The report, dated Jan. 7th, 1892, from the delegates of the two Colleges, on the five years' course of medical study and examination, was read, approved, and adopted.

The Secretary reported that no dissertation had been received on "The Pathology and Treatment of Diseases of the Knee-joint," the subject of the Jacksonian Prize for the past year; or on "The Anatomy of the Third, Fourth, Fifth, and Sixth Cranial Nerves in the Vertebrata," the subject of the Collegial Triennial Prize.

The resignation of the Morton Lectureship by Mr. O. Pemberton was accepted, and the lecture will be given by Dr. G. Sims Woodhead on the 5th of May next.

A letter of the 14th ult. from Mr. C. S. Sherrington, hon. secretary of the Physiological Society, deprecating any curtailment in the proposed five years' curriculum of the extent or scope of the courses of Physiology already enforced by the existing requirements of the two Colleges, was read and laid before the Council.

A letter of the 4th inst. addressed to the President, from Sir Ralph Thompson, K.C.B., requesting, by direction of the Secretary of State for War, to be favoured with the views of the President on the suggestions for the mode of conducting the competitive examinations for admission to the medical staff of the army, was read and referred to a committee, consisting of the President, the Vice-president, Sir W. Savory, Bart., Sir W. Mac Cormac, and Mr. Macnamara.

At the request of the hon. sec. of the National Leprosy Fund, the Council authorised Mr. Hutchinson and Mr. Macnamara to continue to serve as its representatives on the Special Committee.

A letter of the 12th inst. from Mr. H. G Howse was read, resigning, in anticipation of the termination of his period of office on Feb. 10th next, his appointment as a member of the Court of Examiners, his resignation to take effect from the completion of the Pass Examination for the membership, commencing on the 15th instant, and stating that he is a candidate for re-election.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on the 11th inst.:—

Anatomy and Physiology.—Michael J. Halton, student of Yorkshire College, Leeds; William W. Hoare, Extra-mural Academy, Edinburgh; Redmond J. Roche, Royal College of Surgeons, Ireland; William Tregenza, of Sheffield Medical School; Wm. H. Rowlands and John W. Pridmore, of Queen's College, Birmingham; James Fleming Baxter, of Westminster Hospital; and Claude F. Druitt, of Bristol School of Medicine and Mr. Cooke's School of Anatomy and Physiology.

Anatomy only.—George G. Oakley, of St. Bartholomew's Hospital: Basil Pares, of St. Mary's Hospital; Thomas H. Agnew, of University College, Liverpool; Daniel Fogarty, of Ledwich School, Dublin and Mr. Cooke's School of Anatomy and Physiology; Frederick A. L. E. Burgess, of Queen's College, Birmingham; Gerald G. Joynson, Thomas L. Webster, and William J. Bowden, of Owens College, Manchester; Frank Husband, of Bristol Medical School and Mr. Cooke's School of Anatomy and Physiology; Wilford Mettam, of Sheffield Medical School; Moses J. Reubens, of Grant Medical College, Bombay, and Mr. Cooke's School of Anatomy and Physiology; Oswald Challis, of St. George's Hospital; Arthur Emlyn, of University College; and Augustus P. Dantes, of Charing-cross Hospital.

Physiology only.—William C. Gent, of Bristol Medical School; Edward J. E. Coop, Horatio C. W. Wood, and Karl F. Cherry, of Queen's College, Birmingham; Matthias Bailey and John D. McD. Newlands, of University College, Liverpool; Edward Brabazon, of Trinity College, Dublin; William Mansergh, of Owens College, Manchester; Richard A. Fegan, of St. Bartholomew's Hospital and Mr. Cooke's School of Anatomy and Physiology; Richard B. Power, of St. Thomas's Hospital; John W. Sweetlove, of Guy's Hospital; and William B. Murray, of King's College.

Passed on the 12th inst.:—

Anatomy and Physiology.—Arthur F. A. Flower, Gilbert H. W. Ellacombe, and Frederick W. Gale, of St. Bartholomew's Hospital; Stanley S. Argyle, of Melbourne University; Harry F. W. Armstrong and Frederick S. Collard, of St. George's Hospital; Allen Hair, of University College; Francis J. Brakenridge and Thos. G. Nicholson, of St. Thomas's Hospital; Henry R. Walker, of King's College; and Austin C. Fry, of Guy's Hospital.

Anatomy only.—Alfred N. Wilde and Percy W. G. Shelley, of St. Bartholomew's Hospital; Arthur S. Matthews, of St. Thomas's Hospital; Charles N. Barton, of St. George's Hospital and Mr. Cooke's School of Anatomy and Physiology; and Sylvestre A. Francisco, of King's College.

Digitized by Google

Physiology only.—Morgan D. Blake, of Owens College, Manchester, St. George's Hospital, and Mr. Cooke's School of Anatomy and Physiology; Edward A. McAnally, of St. George's Hospital; Thomas S. Farncomb, of Trinity College, Toronto, and Mr. Cooke's School of Anatomy and Physiology: and Sydney M. Meyrick, of St. Mary's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having previously passed the necessary examinations, and having now attained the legal age of twenty-five years, were at the quarterly meeting of the Council on the 14th inst. admitted Fellows of the College:—

Edmund Wilkinson, L.R.C.P. Lond., Queen's-terrace, W. Diploma of Member dated Aug. 2nd, 1888.

Ernest William Gurney Masterman, L.R.C.P. Lond., St. Bartholomew's Hospital. Diploma of Member dated Feb. 12th, 1891.

SOCIETY OF APOTHECARIES OF LONDON.—At the recent Primary Examination the following candidates passed in the subjects indicated:—

Part I.

Chemistry, Materia Medica, Botany, and Pharmacy.—A. W. Fyffe, Galway and Belfast; J. Scarr, Littlebrough; G. H. Wilkinson, Queen's College, Birmingham.

Chemistry.—L. M. Blake, Royal Free Hospital.

Materia Medica, Botany, and Pharmacy.—A. Hilton, Owens College, Manchester; A. W. Taylor, Edinburgh University; E. Wright, Queen's College, Birmingham.

Materia Medica and Botany.—F. T. Cole, King's College.

Pharmacy.—E. C. Bond and E. E. Evans, Royal Free Hospital; F. Mannin, Dublin.

Part II.

Anatomy and Physiology.—R. R. P. S. Bowker, Middlesex Hospital; W. J. H. Dawson, St. Thomas's Hospital; G. H. Pooley, Cambridge University and St. George's Hospital; G. H. Proctor, London Hospital; S. Smith, Middlesex Hospital; W. E. Stanton, Cambridge University and London Hospital; E. P. Staples, Cambridge University and St. Mary's Hospital; F. W. Sell, Cambridge University; F. A. Storr, Yorkshire College, Leeds; S. A. Stride, London Hospital; A. W. Taylor, Edinburgh; J. Thornton, London Hospital.

Anatomy.—S. Foster, St. Bartholomew's Hospital; A. E. Freer, St. Mary's Hospital; E. Grange, Edinburgh University; F. R. Heap, Bristol; T. Hopps, Owens College, Manchester; F. H. Humphris, Edinburgh University; T. E. Johnson, London Hospital; J. Joule, London Hospital; G. W. Pauli, Bristol; A. J. Pollard, Leeds; C. J. Underwood, Charing-cross and London Hospitals; A. Whitby, Dublin.

Physiology.—R. K. Bayley, St. Mary's Hospital; E. T. Fitzpatrick, Dublin; T. Gregg, St. Bartholomew's Hospital; F. R. Hargreaves, Owens College, Manchester; J. A. F. Hatch, Dublin; A. Hilton, Owens College, Manchester; E. S. L. Lovell, Charing-cross Hospital; A. C. McLean, King's College; J. B. D. St. Cyr, St. Bartholomew's Hospital; J. J. Winn, London Hospital.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the directors held on the 12th inst., T. Russel Pickthorne, Esq., Inspector-General, in the chair, the sum of £56 was distributed among the several applicants.

THE REVENUES OF LONDON CHARITIES.—According to the "Classified Directory to the Metropolitan Charities," the total revenue for the past year of the charitable institutions having their headquarters in London amounted to over six millions sterling—or, to be precise, £6,060,763. This total included £2,658,212 for home and foreign missions; £200,251 raised on behalf of the blind, deaf and dumb, incurables, and idiots: £655,790 for hospitals; £504,423 for pensions and relief of the aged; £750,000 for the Salvation Army, and £130,000 for the Darkest England Fund.

CLERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE COMPANY.—The directors of this company have issued a bonus report announcing the thirteenth division of profits among the members and policyholders of the Society. The valuation has upon this occasion been made upon the extraordinarily stringent basis of interest assumed to be earned as 2½ per cent., and mortality assumed to be conformable to that exhibited by the tables known as H^{M} and H^{M} 5. The funds of the Society have during the past quinquennium actually earned a little over 4 per cent., and the deaths actually recorded have numbered fewer than 72 per cent. of the number which might upon the assumed basis have been expected to occur. In respect of both these matters, therefore, it is confidently anticipated that the next quinquennium will exhibit a great improvement upon the calculated figures, and that future surpluses will be commensurately large. On the present occasion the directors are able, notwithstanding the very conservative policy which they have adopted, to divide a large sum by way of bonus, and the share in this division which falls to the policyholders is increased by the circumstance that the shareholders have consented to a limitation of the amount of their share in the divisible surplus.

FOOTBALL CASUALTIES.—A youth aged eighteen, whilst playing football last week on the Wilford Grove football ground, fractured his leg, and was conveyed to the Nottingham General Hospital.

ESSEX COUNTY COUNCIL.—Mr. Edward Tidman, C.E., F.S.I., of Westminster, has just been appointed by the Technical Education Committee of the Essex County Council lecturer on Hygiene, and will shortly commence a course of lectures under their auspices.

CLIMATOLOGY.—The council of the Royal Meteorological Society have arranged to hold at 25, Great George-street, S.W. (by permission of the president and council of the Institution of Civil Engineers), from March 15th to 18th, an exhibition of instruments, charts, maps, and photographs relating to climatology.

OLDHAM INFIRMARY.—The Board of Governors of this institution have opened an Eye Department, and at a recent meeting Griffith Apthomas, M.B., C.M. Edin., was elected eye surgeon. There is an honorarium of £30 per annum attached to the office, which is tenable for eight years, with the privilege of re-election.

DIPHTHERIA AT FINSBURY BARRACKS.—In consequence of many cases of diphtheria having occurred since last August amongst the permanent staff of the 4th Battalion Royal Fusiliers (City of London Militia) and their families, quartered in the Finsbury Barracks, the War Office has ordered the whole of the men and other occupants of the place to be moved to the Milton Barracks, near Gravesend.

UNIVERSITY OF CAMBRIDGE: DIPLOMA IN PUBLIC HEALTH.—Mr. Robinson announces a course of practical instruction in Hygiene for the Public Health diploma examination in the Lent term, beginning Jan. 20th; and also a six months' course in the same subject, beginning April 20th. Applications may be made to Mr. Robinson at the University Chemical Laboratory, Cambridge.

GENERAL PRACTITIONERS' ALLIANCE.—The committee appointed at a meeting of the General Practitioners' Alliance to arrange the details for a complimentary dinner to Dr. F. H. Alderson and Mr. George Brown, president of the Alliance, in recognition of their services in contesting the recent election of direct representatives to the General Medical Council, have decided that the dinner shall take place at the Holborn Restaurant on Thursday, the 28th inst., at 7.30 P.M. We are requested to state that members of the profession who wish to be present should send their names before the 25th inst. to the hon. secretary, Mr. Campbell Boyd, 108, Denmark-hill, S.E.

PRESENTATION.—Mr. William Francis, L.R.C.P. Lond., M.R.C.S., on his relinquishing the position of resident house surgeon at the West Ham Hospital, Stratford, which he had held for upwards of ten years, has been presented by his medical colleagues on the staff and friends with a handsome operation case and a purse containing thirty-two guineas, as tokens of esteem.—Mr. F. H. Forshall, L.R.C.P. Lond., M.R.C.S., M.R.C.P. Edin., of Highgate, has been presented by his patients and friends with several pieces of old silver plate, and an artistically illuminated address in an album form, bearing the names of all the subscribers, as tokens of their esteem, and as a recognition of his unfailing generosity to the poor during a residence and professional career in Highgate for nearly thirty years.

IMPORTANT SHIPPING CASES.—Capt. J. L. Parfitt, master of the ss. *Clyde*, appeared at Bow-street police-court on Friday last to summonses taken out at the instance of the Board of Trade for contraventions of the Merchant Shipping Act, by neglecting to make entries in the official log-book in cases of illness, and the nature and treatment thereof. From the evidence adduced it appeared that the *Clyde* was bound from Bombay to Plymouth, and that an outbreak of influenza occurred amongst the crew, owing to which some of them were incapacitated from duty from three to seventeen or eighteen days. The surgeon reported the matter to the captain, but the latter failed to record it. Mr. Vaughan imposed penalties of £1 and costs in three cases, and £5 and costs in a fourth. He was asked to state a case, but declined.—A similar action to the above is being taken by the committee of the Cardiff Port Sanitary Authority against the captain of a vessel for discharging a man suffering from small-pox without giving notice to the authorities.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

CARPENTER AND DUKES FUND.

THE following additional subscriptions to the above fund have been received:—

Drs. Ord, Harrison, and Burgess	3	3	0	Surgeon-Major Poole	0	10	0
Dr. Neale	0	10	6	Dr. Green	0	10	6
Dr. Rand	2	2	0	Mr. H. Cleaver	2	2	0
Mr. Wilson	2	2	0	Mr. S. B. Mesquita	0	10	6

16, George-st., Croydon, Jan. 12th, 1892. WM. F. COLES, Treasurer.

Etiquette.—We recognise our correspondent's motives in his question. We strongly advise him not to insert such additions and descriptions in his bills. They are unusual, and would look like advertising.

A. W.—We have no special information to give. Our advertising columns might be consulted.

J. W. F. is referred to a general notice given above.

ACUTE RHEUMATISM AND THE TEMPORO-MAXILLARY ARTICULATION.

Mr. Hugh Lane of Bath writes on this subject, in reply to Mr. Flemming, as follows:—

"What I hoped to convey was that in a very large number of observations I found that the temporo-maxillary joint was never implicated in our rheumatic arthritis—an arthritis having its origin in acute or subacute rheumatism, whether gradually merging into the arthritis or occurring some considerable time after. This disease possesses positive and incontestable features of its own sufficient to justify me in placing it under a different heading from chronic rheumatoid arthritis, which we have shown to have no connexion with rheumatism, but which is closely allied to struma and phthisis, and often with hereditary history of gout. In this disease it is a common thing to find the temporo-maxillary joint affected, and when monarthritis exists especially is this the case (monarthritis being rare in our rheumatic arthritis, except in the form following gonorrhœal rheumatism)—so much so that I have now begun to look upon the disease as diagnosed with a comparative degree of certainty by calling it rheumatoid arthritis, should the temporo-maxillary joint be at all implicated. This is what we have seen to be the case by actual experience. We have, in fact, proved that an important connexion exists between this joint and rheumatoid arthritis. The value of correct differentiation between these conditions is paramount when the question of treatment arises—as, for instance, in the great difference in the dietetic treatment of rheumatic and rheumatoid arthritis. In the former it is advisable to refrain from nitrogenous articles of diet—sugar, porter, beer, &c.; but in the latter there seems to be no indication for their interdiction, rather the reverse—in fact, the diet should be generous. Discrimination should be exercised more in rheumatoid arthritis; and not following out this system has, I feel convinced, occasioned much harm. The idea that rheumatism plays a part and is treated accordingly exerts to an enormous degree a very baneful effect in cases of rheumatoid arthritis; while, on the other hand, treating the strumous tendency by cod-liver oil, arsenic, steel, &c., is productive of the very best results. Therefore I still think that the prominence given to connexion between this joint and rheumatism is a step in the wrong direction, and liable to do harm and cause confusion by connecting with rheumatism the only joint that appears to enjoy immunity from the results of the disease, but which, on the contrary, is a most valuable diagnostic agent of rheumatoid arthritis."

Mr. Josiah C. Carter.—Our correspondent should have been called, as far as we can gather from his statement. The coroner has discretion in the selection of medical witnesses in such cases. But it is reasonable to call the practitioner who was sent for and saw the case first. We blame the coroner rather than the police-surgeon.

"SPIRIT WRITING."

To the Editors of THE LANCET.

SIRS,—The paragraph entitled "Spirit Writing in the Fifteenth Century" in your issue of the 2nd inst. induces me to think that you may find the following notice interesting.

In a work entitled "Introductio in Chaldaicum Linguam, &c.," by Theseus Ambrosius, 1539, fol. 212 b, is given the form of conjuration by which Ludovicus Spoletanus invoked the devil to answer clearly and intelligibly a certain question about treasure and where it was to be found. Hardly had the magician laid down his pen when it was taken up into the air, and certain characters were swiftly written on the same paper—"Scribentis vero manum nullus comprehendere poterat." The author states that this was told him by one who was present, and who, moreover, left him the actual archetype, a facsimile of which he gives. Unfortunately, it was not clear and intelligible, and threw no light on the question. I believe the Bodleian Library has a copy of the book, in which the page with the devil's autograph has been pasted over, doubtless as something uncanny.

I am, Sirs, yours faithfully,

Jan. 7th, 1892. T. K. A.

INFLUENZA OR EPIDEMIC COLD.

WE are indebted to a correspondent for the following extract from the *European Magazine* of December, 1813:—

"Influenza or epidemic cold. Such is the term given by medical gentlemen to the disorder now so prevalent in this country—sometimes fatal in its results among children. 1st. Its general symptoms are rigor, or shivering, as in an ague, intense sneezing, running at the eyes and nose, hoarseness of voice, pains in the head, chest, and limbs, oppression on the lungs, and astonishingly rapid respiration at night, with intermittent fever and spasmodic affections during sleep. 2nd. Its certain cure is effected by a gentle emetic of ipecacuanha, frequently aided by small cups of some warm tea or plain water, and a dose of strong infusion of senna on the following day. An ounce of manna dissolved in half a pint of spring water may be taken in a tablespoonful at one time whenever the cough is troublesome. 3rd. The diet should be roasted apples, broths, barley-water, sago, tapioca, or weak gruel. 4th. The clothing warm, but not heavy. Flannel underdresses are highly beneficial; a flannel shift at night has proved essentially useful also. A slight coal fire in the nursery and in the bedroom is indispensable—not to heat, but to dry the air of the chamber."

Dr. Barrs.—We know of no trustworthy work on the subject.

Digitized by Google

KING'S COLLEGE.

WE are desired by the Dean of the Medical School to ask any old students who may receive applications for pecuniary assistance to communicate with him.

Misnomer.—Our correspondent need scarcely send either a written or lithographed letter on the subject. It will suffice to explain to his friends that he is not responsible for the description, and to correct the same for next year. It would be hard to blame medical men for what appears in local directories.

Lex.—The reasonable fee per visit would be one guinea.

ERRATUM.—The name of the writer of the short paper on p. 86 of our last issue is Richard Lake, F.R.C.S., not *Robert* Lake.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Auld, Glasgow; Dr. Austin; Dr. Armstrong, Liverpool; Messrs. Allen and Hanburys, London; Mr. J. G. Barford, Wokingham; Messrs Back and Co., Bishopsgate; Mr. G. S. Bigg, London; Messrs. Bell and Son, London; Mr. Birchall, Liverpool; Mr. Burgoyne; Mr. Bamster, Darwen; M. INFLUENZA:
APPROVED THERAPY.

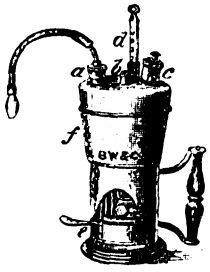
HOOKER'S CHLORIDE OF AMMONIUM INHALER.

THE beneficial effect of inhalations of Ammonium Chloride have been long known to the Medical Profession, and the only objection to its more extensive use has been the high cost of instruments for the inhalation of Ammonium Chloride Vapour. We have, however, at the instance of Dr. HOOKER, introduced a portable pipe inhaler. It is composed throughout of earthenware. The bowl of the pipe contains an inner vessel, perforated at the base, to promote combination of the vapours, and is divided down the middle by a septum. In the base of the bowl itself there is placed a sponge which, when saturated with water, thoroughly washes the fumes. This Inhaler possesses the following advantages over any temporary apparatus. It is extremely portable, and not liable to get out of order easily. It may be thoroughly cleansed by washing, and is moderate in price. This Inhaler may be employed by patients in any position, or while walking, sitting, or reclining. The Inhaler, together with two stoppered bottles, containing Hydrochloric Acid and Solution of Ammonium, for use with the instrument, is supplied to the profession at 5s. each.

The VEREKER CHLORIDE of AMMONIUM INHALER has been reduced in size, and is now supplied packed in an elegant little leatherette case, which makes it very convenient for patients travelling. The special advantages of this inhaler, as pointed out by Dr. MACNAUGHTON JONES (vide "Diseases of the Ear and Naso-pharynx"), are that it may be employed continuously without recharging at each time of using. It yields absolutely neutral vapour, and being simple in construction is easily manipulated by the most ignorant patient. The Vereker Chloride of Ammonium Inhaler is supplied to the profession at 5s. each.

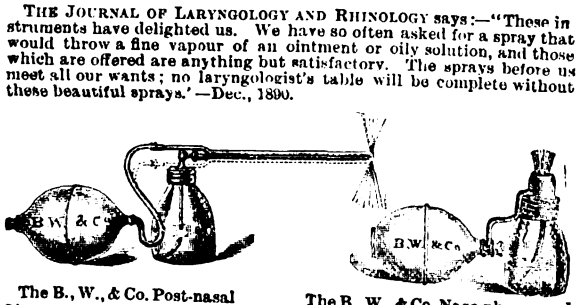
THE MENTHOL ORO-NASAL INHALER.

This little instrument consists of a forked glass tube, fitted with vulcanite nozzle pieces. The thick part of the tube is filled with absorbent pinewood, the menthol solution or other volatile medicament being poured in at the wide end until saturation. The nasal pieces having been inserted in the nostrils, an inspiration is taken, and the air is drawn through the wide tube and becomes impregnated with the volatile inhalant. Inhalations of menthol (menthol ised air) are of the greatest value in the treatment of Hay Fever, Rhinitis, Coryza, Nasal Catarrh, &c. The Menthol Oro-Nasal Inhaler is supplied complete in case with menthol solution and camel hair brush at 3s.



THE HOT AIR INHALER.
AS SUGGESTED BY SIR MORELL MACKENZIE.

Recommended in dry pharyngitis, *Influenza*, laryngitis, bronchial catarrh, ozæna, phthisis, &c.



EXPLANATION.—*a*. Box with sponge for inhalants. *b*. Inlet for air. *c*. Safety valve. *d*. Thermometer. *e*. Spirit lamp. *f*. Boiler.

Sir MORELL MACKENZIE has observed in a very large number of cases that where inhalations of medicaments combined with steam are taken by patients the vapour condenses on the tongue and palate, and seldom reaches the pharynx, trachea, and larynx. Observing this defect, he has designed a simple method whereby patients can inhale volatile medicaments together with the heated air from the instrument figured in the annexed drawing. Patients who have taken inhalations of terebene and terebinthinates evidently inhale these volatile substances into the air cells of the lungs as the distinctive odour characteristic of the absorption of these has been observed in the urine four hours after inhalation. The Hot Air Inhaler (B., W., & Co.) is supplied to the Medical Profession at 14s. each.

THE B., W., & CO. OINTMENT ATOMISER.

THE JOURNAL OF LARYNGOLOGY AND RHINOLOGY says:—"These instruments have delighted us. We have so often asked for a spray that would throw a fine vapour of an ointment or oily solution, and those which are offered are anything but satisfactory. The sprays before us meet all our wants; no laryngologist's table will be complete without these beautiful sprays."—Dec., 1890.

The B., W., & Co. Post-nasal Ointment Atomiser, 8s. 6d. each.

The B., W., & Co. Naso-pharyngeal Ointment Atomiser, 5s. 6d. each.

Mr. LENNOX BROWNE recommends inhalations of menthol by these means in INFLUENZA, rhinitis, and irritable or inflamed conditions of the naso-pharynx.

Dr. MACNAUGHTON JONES ("Subjective Noises in the Head and Ears") says:—"A solution of menthol may be made by dissolving one part of menthol in Paroleine (B., W., & Co.), 7 parts; this is preferable, as it does not turn rancid by keeping. This bland, neutral, and tasteless oil is a ready solvent for all essential oils—menthol, thymol, salol, iodoform, and creosote."

Paroleine is supplied to the Medical Profession in 4-oz. bottles at 9d. each.

ICHTHYOL.

Dr. LORENZ, of the German Army Hospital Department, records in the DEU. MED. WOCH. for 1890 the remarkable preventive influence of Ichthyol in the treatment of Influenza during that epidemic. The plan adopted by this author was to make a 2 per cent. solution of Ichthyol in boiling water, and the person attacked to inhale the vapour for a period of from five to ten minutes frequently, at the same time administering internally Ichthyol in capsules (four minims each), two thrice daily. This treatment never fails to abort an attack, and at the present time in this country has proved of decided advantage for the same purpose. Ichthyol is supplied in 1-oz. bottles, at 1s. 4d. each; and the capsules (4 minims each) in bottles of 50, at 2s. 3d. per bottle.

A complete Price List and full particulars will be sent to Medical Men post free on application.

In prescribing these products please specify B., W., & Co.—e.g.,

℞ Tabloidi Ammonii Chloridi, grs. iii. Mitte xxv. (B., W., & Co.). Or,

The B., W., & Co. Naso-pharyngeal Ointment Atomiser.

BURROUGHS, WELLCOME, & CO., SNOW HILL BUILDINGS, LONDON, E.C.

"Palatinoids" consist of the pure drug contained in an envelope of pure jujube basis. There is no necessity for excipient or antoxidising agent. The drug is freed from deleterious atmospheric influences or chemical decomposition. Their shape and pleasant taste render deglutition easy. Can be administered where pills cannot be taken. The most scientific form of medication ever invented. The portability and convenience of pills with the efficacy of a mixture. Certainty of action. The full therapeutic effect of the medicament. Invaluable to the practitioner for the administration of nauseous medicines to delicate patients and children. Accurate, portable, and scientific.

"Bi-Palatinoids" for the administration of incompatible ingredients and chemicals which in contact undergo decomposition. The most scientific method of administering Ferrous Carbonate (Blaud's Pill), Phosphate, and Arseniate. The only form in which these drugs can be prescribed without the presence of the inert salts. They ensure reliability and certainty of effect. We would especially point out to Medical Men that if the chemicals necessary for the production of pure Ferrous Carbonate (Blaud's Pill) be mixed, decomposition must and does occur. This may be seen by mixing the exsiccated salts, keeping in a dry stoppered bottle, and testing after the lapse of a day or so for the ferric radicle. In the "Bi-Palatinoid" the ingredients are kept apart, and the desired salt is formed fresh and unoxidised in the stomach.

Cream of Malt (Oppenheimer), **Cream of Malt, Oil, and Hypophosphites** (Oppenheimer), differ essentially from the many preparations of Malt Extracts upon the market in their fine golden colour, agreeable taste, and superiority of medicinal effect. CREAM OF MALT (Oppenheimer) is an invaluable medicine and food in Phthisis, Bronchitis, Rickets, in all forms of disease where waste of tissue, bone, or muscle occurs. Rich in phosphates, albuminoids, and diastase; amylaceous digestive; dietetic corrective; mild laxative; an invaluable food after Influenza. CREAM OF MALT, OIL, AND HYPOPHOSPHITES (Oppenheimer) holds the Cod-liver Oil and Hypophosphites in a perfect state of solution. Effectually disguises the nauseous flavour of the oil. Can be administered where the oil alone cannot be tolerated by the stomach. Valuable food during illness and convalescence.

Liq. Euonymin et Pepsin Co. (Oppenheimer) combines the medicinal virtues of the Euonymin with the proteolytic properties of Pepsine. An excellent cathartic, diuretic, hydragogue, antiperiodic, and digestive. May be used with advantage in the distressing symptoms of irritative dyspepsia, with atony of gastric or intestinal muscular layers, in relieving the pain accompanying gastric carcinoma, pyrosis, and in dyspepsia with water brash. It may safely be prescribed in all forms of flatulence and insufficiency of bile secretion. The medicinal virtues of the Euonymin are extracted and rendered soluble. This preparation does not cause intestinal irritation.

Liq. Cauloph. et Pulsatillæ Co. (Oppenheimer) acts directly upon the utero-genital organs as a sedative and tonic, and will be found specific in all cases of Amenorrhœa, Dysmenorrhœa, Leucorrhœa, Prolapsus Uteri, and premature cessation of the menses. In "change of life," Passive Hæmorrhage, Vaginitis, Urethritis, and Hysteria it is particularly valuable, and has been successfully prescribed in atony of the uterus after parturition. It likewise prevents the tendency to repeated successive miscarriage, and by its tonic action restores the general functions of the system; it should, therefore, be administered continually during entire gestation where abortion is feared.

The Harveian Lectures

ON

COMMON NEUROSES, OR THE NEUROTIC ELEMENT IN DISEASE AND ITS RATIONAL TREATMENT.

Delivered before the Harveian Society of London, Nov. 19th and 26th and Dec. 2nd, 1891.

BY JAMES F. GOODHART, M.D., F.R.C.P.,
PHYSICIAN TO GUY'S HOSPITAL.

LECTURE II.

GENTLEMEN,—To-night we pass from the neurotic conditions that concern the sentient being as a whole, and which I have in consequence termed "cerebral neuroses" for want of a better term, to others that have for the most part a more local bearing. The distinction is of course an artificial one, but it enables me to group the cases better, and has other conveniences as well. We shall concern ourselves, then, to-night with troubles of the thoracic cavity, or rather with respiratory and circulatory neuroses. And the first group of cases that I have to mention is distinguished by a disposition to more or less severe attacks of paroxysmal sneezing. Such cases are by no means uncommon, and they are very troublesome. I give a short note of some. A young lady comes of highly neurotic stock. Her mother suffers from bad sick headaches, and as these have become less severe they have been replaced by other neuralgic turns. This patient's brother, whom I saw, has had curious neuralgic pains in the abdomen when a child, the diagnosis of which was only arrived at after some long period of watching. Two other of the children have bad nightmare. This child is aged fifteen; she is growing fast. She is brought for what are called bad colds, but when the account of them is detailed, the attack appears to consist of sudden severe paroxsyms of sneezing, and her nose runs freely. The attacks of sneezing are so severe that they make her quite ill, and she has to go to bed for a day or two, by which time she recovers herself, and she is well for a time. She has a thin skin, and easily gets chilblains. A second case is that of a lady of thirty, who is much troubled with violent fits of sneezing and nose-running, which last about two hours every morning. There is no doubt that she is a neurotic: she has bad headaches and noises in the ears, and she already has grey hair. Two others were women, and both were asthmatic. Another case, a man, has his attacks almost every morning, more in the cold weather than in the warm, and the cold passes off as the morning wears on, mostly soon after breakfast; but before that time is reached he has used up a couple of handkerchiefs. In a little girl of six "such bad colds come on quite suddenly in her nose" A lady of forty is always taking cold. She has been to no end of doctors about her throat, and has used all sorts of vapours and inhalations. Her fingers "die" occasionally, and when her body is warm her fingers and toes are cold. She has most bothering attacks of sneezing, and is often hoarse. The sneezing comes on mostly at night, and in consequence of it she wraps her head in a shawl whenever she goes out, and takes great care of herself; but whenever she is in a good climate she is quite well. Another case is a woman aged twenty-nine. Her maternal grandfather had hay fever and asthma. She has had bad sneezing attacks for years. The attacks commence in the early morning and go on till about 11 A.M., and then cease suddenly; she has of late had much asthma. The last case I shall allude to is that of a gentleman who has been long in India. He has had malaria once or twice, and an attack of eczema once in India, and for twenty years or more he has had severe periodical attacks of sneezing. He was sent to me for transient glycosuria, and he did not allude to his nose much. I fancy he had had enough treatment for that affection, for he had fallen (unluckily, as I think, for him) into the hands of someone who had done despite to his nasal mucous membrane by means of the galvano-cautery.

These cases are very interesting; they are closely allied to hay fever, if they be not part of the disease that goes by that name. They are closely related also to spasmodic asthma, as this case will show. A man of twenty-six has had asthma since three years old. His attack often begins in the early morning by passing from a warm to a cold room, which brings on a violent attack of sneezing. This may last from thirty minutes to two or three hours, and sooner or later seems to pass down his bronchial tubes to his lungs, and then to produce a short attack of asthma, which, however, generally passes off on taking a cup of hot coffee. I am not sure, too, that they may not have some relation with Raynaud's disease. But however this may be, the affection is a purely neurotic one, and in no one of these cases was there any local disease of the nose. Nor, indeed, if we look at the history of the attack, was there likely to be, for the attack comes on in almost all the cases with the greatest suddenness, reminding one much more of the suddenness of the explosion of a nervous discharge than of the onset of an inflammation. And I think, if we study the nature of these attacks, the more one becomes convinced that the real disease cannot be any local organic change, it comes and goes so rapidly. It has been said indeed, and I dare say with truth, that this state is immediately due to an erectile condition of the mucous membrane of the turbinated bones; but if we allow that this is so, such a state of things is, after all, only an exaggeration of a physiological condition, and in no sense a local disease. I make a great point of this, because these cases are in the present day being treated by local measures of some considerable severity. I hear of turbinated bones being removed for such symptoms as I have narrated, and more often of the galvano-cautery being applied. Now I must not say that treatment of this kind is never necessary, for "never" is a word that seems to have crept into the language of men by mistake, and almost the only time it has justified its existence, and can be used with absolute appropriateness, is when we say of it that it is never absolutely true. But I think we should remember, in making use of severe measures of this kind, that we are only treating a symptom, and from the nature of the case adopting a means that is very unlikely to prove of any permanent good. I feel bound to add that in my own opinion all means of this kind are meddlesome and bad surgery, and will never bring us any credit; I will go further, and say that they come perilously near trailing an honourable calling in the mire of quackery. In saying this I pass to another neighbouring neurosis that is not altogether above a similar suspicion—the disease that goes by the name of "clergyman's sore-throat." I must apologise to the laryngologists for putting them so much in the forefront of my offence, but I dare say they will consider what I have to say is only the result of ignorance. I suppose we all come more or less across this affection, and if your experience is at all like mine, it is of this kind: it occurs in nervous persons; they are often overworked, and want a holiday. That is a very common complaint, and requires no advice from a specialist; but it often enough occurs in the country parson who has an easy life and less than enough to do. Now I have talked to several of these people, and the complaint they make is that after a simple reading exercise such as is required by the church services, the voice goes, or more commonly, I think, that they feel exhausted. I do not remember to have seen it in anyone who has been a long-winded preacher, or in one who has the gift of energetic extempore discourse; it is a disease of the feeble lack-lustre man or of the highly nervous. From talking to them I have come to the conclusion that there are some who look upon the exercise of the voice as an exhausting thing, and that when they had gone through the very modest exertion of reading the prayers they were somehow used up and virtue had gone out of them. The idea is expressed in this extract of a letter received only the other day from a young effeminate man, who has a good voice, and is going in for singing: "I forgot to ask you," he writes, "if I may bathe and swim in the season, because I have been told that it is a very weakening pastime for one who wishes to cultivate the voice." The idea obviously is that the act of singing uses up the vital energy, and that there is no sufficiency for any expenditure on other calls. So far as my experience goes, I have examined these throats many times, and have never seen anything the matter with them; and I am certain I have seen these people having a nice time of it on the Riviera, nursing their throats, and with an air of respectable delicacy about them, when all they required was a good tonic, with the reassurance that they

Digitized by Google

might with perfect safety return to their work if only they would take care to make it a work of their *will* and not of their *emotions*.

Now these are emphatically not the cases to put through a course of inhalations, of paints, of electric tickling—worse still, of galvano-cautery. They will go in for anything we advise them, and it is marvellous to me how docile, not to say imbecile, some of these patients are in abdicating all the seat of their reason. But in saying thus much it may perhaps be thought that I am speaking in an exaggerated way; for, after all, the voice and the throat are sensitive parts, and we have abundant evidence in great singers that most trivial causes may upset them. I do not think what I have said touches that question. A singing voice brought to the perfection of a great public singer is a very touchy thing no doubt, but the ordinary avocations of those who suffer from their throats—and though I have given it the common name, yet it is by no means confined to the clergy—ask no service that can be compared to the evolutions that a larynx of that kind goes through. The ordinary work of the voice, even for those who are called to address public meetings or talk much, is no such excessive tax. Moreover, it is no uncommon thing to find ordinary people become hoarse after reading or singing for a short time. But if their nerves are of proper string, they do not for that reason rush off to the throat doctor; rather do they bear the ills they have than fly to others that they know not of. Nor do these things mean any real delicacy: I assert most positively that they are absolutely independent of the general health, and are due no doubt to some local incoördination of the several structures concerned. This may arise from several causes. It may be from fatigue of the muscles; may be from inability to adapt the parts properly; it may be from some little swelling of the mucous surface under the stimulus of use; from a little hypersecretion under like circumstances, and so on. My own conception of the disease would perhaps be that it is a mild hybrid between a costermonger's throat on the one hand and the functional aphonia of women on the other. I mean to say that there are, perhaps, about it both the elements concerned in these diseases—a mild, very mild catarrh, we may call it, on the one hand, and a want of nerve force on the other. The former element is so slight that treatment for it is not required: and for the latter nothing more is necessary than a good nerve tonic. I have no objection to a poor hard-worked man of business or a clergyman having a health-giving time on the Riviera, or anywhere else. By all means let them have it if it be necessary; only let it be the remedy for what it is, for a general nerve fatigue. The advice could be then taken or rejected on its merits; but to say you have a delicate throat and must go here or there according as the latest fashion dictates (if it means anything), is a sort of verdict of consumption by innuendo that does not allow the man to be a free agent, and he obeys, often at the greatest inconvenience to others as well as himself, and often at considerable sacrifice. And while I am on this subject I will say that advice with reference to residence seems to be given often in the most reckless and ill-considered fashion, when we remember how little we really *know* about such matters.

I must next allude to the people who are always "catching cold." They are common enough, but here is one such: A man of thirty-nine years. He had ague in his youth when he lived down in Essex, but he has got rid of that, and has had very good health until he went to the East a year or two ago and got fever (he thinks not malarial) on his way home at Athens. Ever since then he has been subject to colds, and his subjection in this respect gets worse and worse. Sometimes he has cold in the head and sometimes it is a sore-throat. The slightest chill brings on an attack. Now colds, or rather a tendency thereto, are due to a neurotic susceptibility in almost all cases. The usual treatment for them is shielding the patient in all possible ways from all changes of temperature; and what is the result? It must inevitably be that, kept from all experience of changes of temperature, the surface loses its accommodative power, and in consequence becomes unduly sensitive to any change. Thus instead of a cure an ever-increasing liability to "colds" results. The man who attempts to keep himself in a uniform temperature in the English climate engages himself in a struggle with his environment in which he will inevitably get the worst of it, and sooner or later he will be crushed if he does not give up the fight. There cannot be any question that the diseases of which I am speaking are the products of civilisation, and that they are gradually evolved out of the trivial ills and troublesome sensations that are the common lot of mankind, by giving way to them in the first instance instead of learning to bear them, which in the end would mean not to mind them. In so far as the inability to bear them is an indication, as it often is, of an enfeebled nervous tone, so far they are proper cases for drugs; but bear in mind that it is always to be medicine *plus* good advice and rudimentary lessons in physiology, and that the latter part of the treatment is the more radical of the two.

And from this I pass to a closely allied disease, to another product of civilisation—viz., spasmodic asthma. Of course this disease may be produced in several ways, but I shall not be misunderstood when discussing it to speak of the several organic causes by which it is brought about, but simply of what is sometimes called true spasmodic asthma, because, forsooth, no definite organic cause can be discovered for its existence. I say, again, no true definite organic cause can be discovered for its production. To say that implies that we have searched for one—and I would not say have searched wrongly,—but what I would say is that in searching for a cause of this kind let us beware of becoming engrossed with the idea that there is a structural change if only we could but find it. In these latter days the search for tangible causes is so successful that it has become absorbing, and there is a definite intolerance abroad of those who talk of functional disease. No doubt, from the point of view of those who attack the citadel of ignorance *ab extra*, functional disease is a cloak for ignorance, and it is too often made the pretext for the wildest notions, the most shameless quackery, and at the best is too often obstructive to material progress. Nevertheless, grounded as I have been in the coarser facts of morbid anatomy by thirteen years' work in the post-mortem room, I consider I have a right to say that there is still a large place in the practice of medicine that is legitimately filled by functional diseases, and that probably there always will be. The huge lunatic asylums that may be seen growing up all around us go a long way towards proving the truth of such a contention, but there are many other diseases along the lines of my present subject, and spasmodic asthma is one of them. When I study this disease in a comprehensive way, it seems to me as nearly certain as can be that it is the direct result of cultivation, and in its worst forms often of our methods of its *treatment*. Asthma can be fostered and nursed into a very terrible disease, and often is so. And, on the other hand, I believe that much may be done to mitigate its severity, to eradicate it altogether, or, at any rate, to divert it into more general paths of explosion, if we make ourselves familiar with its history.

What is the history of spasmodic asthma? The first thing that I learn about it is that it largely occurs in those who have in one form or another a neurotic inheritance, or are themselves clearly of that temperament. I have gone over my own cases from this point of view, and this is the result. Of fifty-one cases (twenty-seven males and twenty-four females), nine only were not evidently neurotic. In eight the disease was hereditary; in ten there was rheumatism in the family; in five a pronounced history of megrim. In others I have noted the existence of diabetes and somnambulism in the relatives. In the patients I note such things as chorea; "a highly nervous and crotchety lady." "If anything goes wrong in business the man is sure to have an attack"; "the attack comes on after any little excitement." A girl of seventeen had convulsions when an infant; another young lady had hysterical aphonia and urticaria, and bad rheumatism at other times; another patient has had urticaria, headache, and asthma. And so the story goes all through the list. I need not take up time by going more into details. But as an amusing illustration of the extraordinary mental feebleness that may be sometimes reached where our ailments are in question, I cannot forbear to tell the following. A lady came to me for asthma, and in the course of conversation said she thought she ought to tell me everything. The confession she had to make was that she had put herself under someone who undertakes to treat disease by correspondence. I asked her what had led her to seek advice from so unreliable a source, and her reply was: "Well, I knew he must be a good man because he advertises in the '*christian*'"!

Another point about asthma has often struck me, too—

Digitized by Google

viz., how seldom, comparatively speaking, it occurs in the lower classes of society. It is chiefly a disease of the middle and upper strata—a disease, I believe, of infancy and childhood as much as of adult life, and, I would add, ought to be confined to those stages of existence. A case of pure spasmodic asthma is quite uncommon in the wards of a hospital, and in so being may be offered as a fact in support of what I advanced in my last lecture—that it is probable that the evolution of neurotic tendencies is proceeding faster in some strata of the people than in others. And when I say this of asthma, I am not sure that in all of what I am going to call its stages of evolution it is much more often absent in the lower than in the upper classes; and, if this is true, then it may go to support my contention that the pronounced disease is eradicated in no small number of cases by the gradual hardening of the nervous system that takes place under the conditions of the struggle for existence that prevail amongst the lower sons of toil. But to make my meaning clear, I must now explain what I consider to be the different phases of spasmodic asthma.

As I look along the seven stages of human life, from its cradle to its grave, I find nothing that at first sight resembles spasmodic asthma at the early periods of life; that is under, say, three or four years. And not finding it, and, further, not seeing any evident reason for its absence, for there is nothing in its symptoms that would betoken it was a disease of a special period, one not unnaturally scans the wide plain of infantile disease, to see if perchance from this point of view some rudiment or embryonic form of the malady can be discovered. I cannot but think that a disease is soon discovered which has points of great similarity, although wanting the most characteristic feature of the mature malady, if so I may speak of it. The disease I have in my mind you all know well. I mean the common gastro-pulmonary fever that any practitioner sees once or twice in every day. Here is the sort of case I mean. A little boy four years old, who comes of a decidedly neurotic stock, and who, moreover, has shown decided evidences that as was his mother in this respect so is he, is quite well on a certain day, and ails a little towards night. His mother says he has got a chill; his father knowing more of the world, perhaps, and altogether having a more critical disposition, is not so sure that the child has not overeaten himself. Anyhow his so-called cold gets worse, a cough comes on, and he develops a sharp fever. The disease, whatever it is, quickly rolls along the bronchial tubes, and when the doctor arrives he has all the appearance of being seriously ill with a sharp attack of bronchitis. To make matters worse, apparently, he is sick several times in the course of the first twenty-four hours, and at the end of that time he is still breathing rapidly and seems very ill. Within a day or two, however, the temperature drops, the acuteness of the chest disturbance subsides, and within three or four days the whole affair is at an end, leaving the little patient hardly worse than he was before the attack commenced. Now, one acute illness of this sort tells us nothing; the disease still might be many things, and the field is left still contested. "My dear," still says the wife, "I am sure the child caught a chill," and a host of reasons are given to prove it, but the father keeps also to his opinion, and declares that the buns he saw his little glutton eating were enough to do a great deal more damage than was the case here, had not the destroying angel stayed his hand. The doctor looks on at this domestic strife and shrugs his shoulders, and departs well satisfied that the illness that threatened so seriously has proved abortive. But by-and-bye the same scene comes over again, and yet again, and the doctor at any rate grows wiser, for he learns then to know his patient's constitution, and he knows that whatever may be the *exciting* cause, the real one lies far deeper in the primordial tendencies of the child. And the experiences of general practice will tell many that I am not drawing upon my imagination in the least, but that the picture is one of the commonest that is met with in the daily round. There can be no question that these sort of attacks occur in particular families and belong to particular children; and, as I have said elsewhere, they are to my mind paroxysmal neuroses, and they are the representatives in babyhood of spasmodic asthma. For some reason or other, which I shall not even attempt to guess at, the respiratory paroxysmal neuroses put on this form in infancy and early life; while that of spasmodic asthma is characteristic of older children and adults. I think, to repeat what I said just now, that in comparison with spasmodic asthma the gastro-pulmonary fever of infancy is quite a common affection; and well it may be, if, as I say, it is the special reaction of the infantile respiratory system to nerve storms of all sorts. But its prevalence also admits of other explanations; one being that as the embryo nervous system grows in health and education it becomes less explosive, and thus the tendency vanishes. Another, that as development goes on other viscera come more into the field, the cyclone is drawn into other regions, and the pulmonary tract escapes.

Now dealing first with the treatment of these infantile cases, over and over again these children have been brought to me because their proper treatment has not been rightly apprehended, because their nature has not been recognised. They have been supposed to be due to cold and chills, and the *disease* has been *treated*, and not the *patient*. But to shield these children from every possible draught, and to keep them at home when there is the least suspicion of the wind being in the east, are not the means to cure them; such only make them worse. It is because they have been getting worse, in spite of treatment, that they are for the most part brought to me. Treatment of this kind begets a more irritable state of nervous centres, and the only way to cure them is to harden them. I need hardly go into the details of their management, they are so common sense and plain; but, in short, they are to have their bath regularly, to be warmly but lightly clad; they are to be taken out into the air as much as possible; and they are, in fact, to undergo a process of hardening and education by which their nervous susceptibilities are to be made less susceptible. As regards drugs, if they have any at all, they are to be such as give tone to the nervous system, such as nux vomica and iron. The treatment of asthma is not otherwise. You will never cure asthma by coddling. It is a local expression of an undue sensitiveness of the nervous system to the changing circumstances of its environment; a phlegmatic power of accommodation that, reacting slowly, reacts too late; and in the meantime the higher centres left unguarded by the laggard signal, and bereft of their natural protection, are stimulated too strongly, and a storm or spasm is the result. Put it in what language you like, that, I take it, is in effect what happens in spasmodic asthma. Supposing, now, that we elect to treat the disease according to the common fashion: we prescribe some local inhalation to the respiratory mucous membrane, which in some one of several ways leads to the cessation of the spasm. What happens is best illustrated, I think, by the infant, who, for each new toy, drops all its old ones; or, perhaps, by the old adage, you cannot do two things at once. The bronchial mucous membrane, stimulated by some powerful aromatic, forgets all about its previous excitement, and between the two stools the patient happily sinks to his much-needed rest. But whether stimulant or sedative, so far as regards the nervous system, the same result accrues—viz., that a sugar plum is put in its mouth and it is told not to be a bad boy again; and with the usual result—that when the sweet is gone it is soon on the look out for another, and another it gets, and so on. In more prosaic language, the mucous surface receives a something that for the time being causes it to ignore the conditions of the environment, at which it had taken offence; but the effect of the drug having passed off, it is more alive than ever to the original discomfort, and again a spasm is set up. Again the drug is repeated and the same order is observed, and so on again, and again, and again, with, however, this important difference, that the interval between the spasmodic attacks grows shorter and shorter as the mucous surface grows more hungry. I take it that the nervous circuit from lung to brain of the old asthmatic who has been addicted to Himrod's treatment or such similar compounds is the exact counterpart of the nervous circuit from nose to brain of the chronic snuffer; but the pangs of the bronchia are the more urgent.

As regards children there is something else to be said. They are not quite so often as adults treated by these patent powders; but they are very generally treated by looking on the disease as the result of cold, and they are boxed up in an over-warm apartment; they are smothered in clothes; they are not allowed to have a decent romp for fear they may get hot and take a chill; and altogether they are only too liable to live a most unhealthy life. Their most saving power, that of accommodating themselves to their environment, is nursed

Digitized by Google

into imbecility, and then the wonder is that they grow worse instead of better. I would venture to point to a more excellent way than that; more excellent, because it is assuredly founded upon a physiological basis; and it is this, to find out by experiment where the child can live best. It is always a matter of experiment this; not the greatest authority in all the world can say for certain, for I say asthma is a functional disease of the nervous system, and it is in diseases of this sort that the individualism of the patient most crops up. Having found a place of residence, turn the child out to grass, in place of keeping it in-doors on all doubtful days; gradually accustom it to be out in all weathers, and make it as perfect an animal as can be in these days, when conventionality is part of the air we breathe, has penetrated to the inmost recesses of our homesteads, and, for aught I know, perhaps even to the pigstye. It is difficult indeed to be a healthy animal in these days; but that is the way to cure asthma in the child, and it meets with a large measure of success. I have seen ample evidence of the ill success of the coddling method to have no doubt which is the better plan, had I no other grounds; but I do believe that those other grounds that I have pressed upon your attention are not unworthy of it.

(To be concluded.)

ABSTRACT OF THE
Lettsomian Lectures
ON THE
SURGICAL TREATMENT OF TRIGEMINAL NEURALGIA.

By WILLIAM ROSE, F.R.C.S.,

JOINT PROFESSOR OF SURGERY IN KING'S COLLEGE, AND SURGEON TO KING'S COLLEGE HOSPITAL.

LECTURE II.

THIS lecture was entirely devoted to a consideration of the various operations on the different branches of the fifth nerve, Mr. Rose passing each procedure rapidly under review. The topographical and deep surgical anatomy of the parts concerned was also discussed, and the various methods of dealing with the division of the fifth nerve were explained at length. Regarding the superior maxillary division, the lecturer described the orbital method and the antral method of exposing and removing large portions of this branch of the fifth nerve. He stated that the third means of dealing with this division of the fifth nerve—viz., the *pterygo-maxillary operation*—was originally suggested by Professor Lücke. He made an oval incision extending from the outer canthus first backwards, and then downwards and forwards; the masseter muscle is then detached from the lower border of the zygoma, and turned down, whilst the zygoma itself is sawn through in front and fractured behind; so that it, together with the temporal fascia attached, could be turned upwards. By carefully dissecting down in front of the tendon of the temporal muscle the spheno-maxillary fossa was reached, and the nerve divided. The parts were then replaced, the muscle being sutured to the zygoma. The results of this method of dealing with the zygoma were extremely unsatisfactory, from the fact that the muscle usually did not unite with the bone, and hence cicatricial deformity and functional weakness were produced. Professors Braun and Lossen introduced a plan to obviate this—viz., by detaching the temporal fascia from the bone, and turning the latter downwards together with the masseter. This procedure removed one of the objections to reaching Meckel's ganglion by this route, but in order to remove the infra-orbital nerve it is necessary to make an additional incision over the site of the infra-orbital foramen. The great advantages claimed for this operation are that the cicatrix will be less obvious on looking at the patient full-face, and the hæmorrhage will be less in that the internal maxillary artery can be secured before the fossa is opened. Moreover the antrum is not opened, and the risk of septic contamination of the wound considerably diminished.

The lecturer, whilst admitting that he had never attacked the second division of the trigeminal in this way, mentioned that an opportunity had recently occurred to him whilst dealing with a case of ankylosis of the jaw of investigating on the living subject its practicability, and he had been much impressed by the ease with which it could be accomplished. He also commented on the statistics which have been published by Segond[1] of eleven cases which had been dealt with in this way by Czerny,[2] Madelung,[3] and himself, though the relief given had not been of long duration.

The third division.—After describing the surgical anatomy of the *third* or *inferior maxillary division* of the fifth nerve, Mr. Rose proceeded as follows:—

"The *inferior dental nerve* can be exposed in three situations—at its exit from the mental foramen, in the dental canal, and above the dental canal. *At the mental foramen* it may be divided by a submucous operation. Its position is easily ascertained—viz., between the bicuspid teeth. The operation, however, is not to be recommended, as the pain invariably returns. The nerve can be reached *in the dental canal* by removing a disc of bone comprising the outer layer of the jaw by means of a three quarter-inch trephine applied over its course about the junction of the ascending and horizontal rami. If the circle of bone be skilfully removed, the nerve and the artery can be seen running together in the bone, and the former lifted on an aneurysm needle. The skin incision for this operation should be made along the line of the jaw, and about half an inch behind it, never over the part to be trephined. Another somewhat similar method of dealing with the nerve is that of Velpeau, who through the same kind of incision trephined the jaw through the ascending ramus, immediately over the dental foramen. At this spot the bone is much thicker below than above, and hence the trephine should not be used when the upper part of the jaw has been divided; the remaining half circle of bone is best detached by means of elevator and chisel. Linhart operates in much the same way, but detaches the masseter by a vertical incision, which is liable, I should fear, to divide all the branches of the facial nerve there present, and consequently lead to paralysis and subsequent facial disfigurement. Gross has recommended the use of the dentist's drill as a means of destroying the nerve in the canal by perforating the jaw. The results of these operations are unsatisfactory, and I have therefore entirely abandoned this method of treating neuralgia of this nerve, always having recourse to the higher operation. The inferior dental nerve has been attacked *just above* its entrance to *the dental canal* in the lower jaw by three different methods, which we may fairly describe as—(*a*) the intra-buccal method; (*b*) the retro-maxillary; and (c) the transmaxillary.

"The *intra-buccal* method is the form the operation originally took; it was proposed originally by Lizars, and performed for the first time by Michel of Nancy in 1856. More recently it has been again advocated by Billroth, but it is commonly known as that of Paravicini." After alluding to the course taken by the nerve under the mucous membrane of the mouth, the operation was described in detail. In criticising it, the following objections were noted: first, the communication of the wound with the mouth, leading to septic contamination, and in one recorded case (Michel) to death from septicæmia; secondly, the limited portion of the nerve which can be excised (Billroth says one inch); thirdly, the difficulty of the operation owing to the want of space; and finally, the possibility of serious hæmorrhage, necessitating, in a few recorded instances, ligature of the external carotid.

The *retro maxillary* operation, or, as it is commonly called, the Lücke-Sonnenburg method, after the two surgeons who originated it, is described by Ullman, who has recently advocated its use, as follows:—The head is allowed to rest on the sound side, or even hanging down over the end of the operating table. An incision is now made along the posterior border of the jaw, and from 1·5 centimetres above the angle to the centre of the horizontal ramus. The branches of the facial nerve to the neck are the only ones of importance divided, but of course the facial vessels will need to be ligatured. The parotid fascia is now incised, and the gland drawn upwards as far as possible. The internal pterygoid muscle is detached by scissors from the mandible, and the entrance to the inferior dental canal is

indicated by the spine of Spix, which should be carefully sought for. The nerve is isolated and divided with scissors peripherally; it is held tense with forceps, and serves, if necessary, as a ready guide to the foramen ovale.

The *transmaxillary operation* is that which promises to be the most effectual, and is, perhaps, that most generally adopted in the present day. It is usually accomplished by deepening the sigmoid notch. Inasmuch, however, as the lingual nerve can also be dealt with by this method, and since both nerves usually need simultaneous division close to the base of the skull, the description of this operation was deferred until the discussion of the methods of reaching the trunk of the nerve at the foramen ovale.

The lingual nerve.—After briefly describing the anatomical relations of this nerve, the method of reaching it through the mouth was mentioned, and unfavourably criticised, although it might be justifiable in some cases of malignant disease of the tongue. Luschka's method of reaching the nerve through the submaxillary region was detailed; but the depth at which the nerve lies was stated to constitute a serious bar to the adoption of this operation. The Lücke-Sonnenburg plan described above could also be applied to this nerve. The lecturer, however, emphatically maintained that all measures directed to this nerve alone are ineffectual, and hold out little prospect of permanent relief.

Division of the nerve at the base of the skull.—Mr. Rose continued as follows:—"Previous to describing the different methods of reaching the foramen ovale which have been proposed and practised, it may be well to examine its chief anatomical relations.

"*Surgical anatomy.*—The foramen ovale is an aperture at the root of the great wing of the sphenoid, close to its junction with the external pterygoid plate. It lies immediately behind and external to this process, and is on a level with the eminentia articularis of the temporo-maxillary joint, being placed at a depth of about one inch and a half to two inches from the surface of the face. The long axis of the foramen is directed backwards and outwards, and at its postero-external margin it is only separated by a narrow neck of bone from the foramen spinosum, which lies at the base of the sphenoidal spine, and through which the middle meningeal artery passes. It will be seen, therefore, that the foramen ovale lies midway between the base of the external pterygoid plate and the spine of the sphenoid, being covered by the origin of the external pterygoid muscle. The internal maxillary artery is superficial to both pterygoid muscles in the majority of instances, lying between the external pterygoid and the jaw and passing into the spheno-maxillary fossa through its two heads. Occasionally the vessel passes between the two muscles and thence to the fossa. This point should be kept in view in any operation upon these parts, as the early ligature of the vessel is most desirable. There is also a large plexus of veins in this region, from which troublesome hæmorrhage is sure to arise. But, however variable the vascular distribution, the dental and gustatory nerves are quite regular in the position which has been already described; emerging from beneath the external pterygoid muscle, they lie upon and are superficial to the internal. To expose these nerves in some way or other must be the first aim of the surgeon, and, this done, they can be traced to the base of the skull with comparative ease and there divided. Three different plans have been suggested and practised for reaching the foramen ovale—viz. (*a*), Pancoast's method, with various modifications as suggested by Salzer, Krönlein, &c.; (*b*) the Lücke-Sonnenburg method; and (*c*) the plan of deepening the sigmoid notch as practised by Mr. Horsley, myself, and others.

"(*a*) Pancoast was the pioneer in this department of surgery, and his first operation was performed nearly twenty years ago. It appears that only one case was treated in this way, but the operation was an important step, and is greatly deserving of record, in that it has served as a basis upon which many modifications have been grafted. He dissected up a rectangular flap comprised of the skin and masseter muscle, and with its base at the zygoma, exposing by this means the temporal tendon, which was then detached from the coronoid process. This process was next removed by cutting pliers close to the ramus of the jaw, and the pterygo-maxillary fossa opened up. The attachment of the external pterygoid muscle was then divided, the internal maxillary artery having been, if possible, previously tied. The third division of the trigeminal could thus be reached as it emerged from the foramen ovale. The disadvantages of this method are that the temporal muscle is very widely detached from the underlying bone, and that the coronoid process is removed. The operator also must have been considerably cramped in his manipulations, as the zygoma was left intact. Its removal or temporary displacement was soon added as an additional step in the operation. Again, the incision was devised irrespective of the distribution of the facial nerve, and the integrity of the duct of Stenson must have been seriously threatened. Of necessity the resulting cicatrix was extremely unsightly. Salzer operated through a curved incision, having its convexity upwards; it extended from just in front of the tragus above the zygoma, and terminated anteriorly at the lower border of the malar bone. This incision passed directly to the bones, and the zygoma was divided by the saw anteriorly at its attachment to the malar, and posteriorly in a line with the eminentia articularis. The temporal muscle was divided by a transverse incision across its fibres a little above the zygomatic arch, and the whole flap of soft tissues, including the loose piece of bone, was drawn down by scraping away with a blunt raspatory the lower fibres of attachment of the temporal muscle to the squamous bone until the pterygoid ridge of the great wing of the sphenoid was reached. Still, keeping close to the bone, by detaching the external pterygoid muscle access was gained to the foramen ovale; this was much facilitated by keeping the mouth open, as by this means the coronoid process was depressed and kept out of the way. There are obvious objections to this procedure; the operator has to work down on the nerve from above, and his manipulations are much hampered by the limited space at his disposal. Necrosis of the zygoma has moreover occurred, but it can be avoided by adopting the precautions suggested in my next lecture.

"Another modification of Pancoast's original plan is that originated by Krönlein[4] in order to reach and divide both the second and third divisions of the nerve at the base of the skull. Inasmuch, however, as this method, with the exception of the skin incision, is practically identical with the preliminary steps of my present operation for removing the Gasserian ganglion, I shall defer a full description of it until my next lecture. In brief, it consists in dividing the zygoma in front and behind, and turning it down with the masseter after releasing it from the temporal fascia; and in dividing the coronoid process with the chisel and turning it up, together with the temporal tendon. The external pterygoid muscle is then detached from the skull and the foramen ovale exposed. The foramen rotundum may be reached afterwards through the pterygo-maxillary fissure, somewhat according to Lücke's method already described. The same objection applies to this as to the former operation, in that it is an unnecessarily severe proceeding when the third division alone is to be dealt with; a similar result can be obtained by the simpler operation of deepening the sigmoid notch. But if it be requisite to divide the second division simultaneously with the third, then this plan may be advantageously employed. Such a step, however, will be rendered unnecessary if the Gasserian ganglion can be safely reached within the skull.

"(*b*) The foramen ovale has also been reached by the Lücke-Sonnenburg, or retro-maxillary operation. Ullmal[5] has recently recorded two cases in which he made use of this measure, and speaks most highly of it, inasmuch as the bones of the face are not interfered with except that it is occasionally necessary to divide the angle of the jaw and turn it temporarily outwards, wiring it subsequently; the superficial nerves divided are of no importance, the scar is placed well out of view, and the movements of the jaw subsequently are less disturbed. I have had no personal experience of this. Mikulicz and Obalinski have proposed to reach the foramen ovale in a somewhat similar way. The former makes an incision from the mastoid process along the anterior border of the sterno-mastoid to the level of the hyoid bone, and then upwards and forwards to the border of the jaw. The skin is now dissected up, and the bone, carefully stripped of its periosteum, is divided by a chain saw behind the wisdom tooth, great care being taken not to open the mouth cavity. The internal pterygoid muscle is now to be detached, and the vertical ramus can then be drawn well outwards, leaving a funnel-shaped opening with its apex at the base of the skull in which

[4] Deutsche Zeitschrift für Chirurg., xx., p. 484.
[5] Wiener Klinik Wochenschrift, June 20th, 1889.

Digitized by Google

the nerves are readily found and traced to the foramen.

"(c) The third method, and that which I consider the best, not only for reaching the foramen ovale, but also for removing the largest extent of these trunks, is that of *deepening the sigmoid notch*, a proceeding modified by Mr. Victor Horsley from Velpeau's original method of trephining the jaw. The following description of the way in which I perform the operation is similar to Mr. Horsley's with a few exceptions, my skin flaps being curved, while his are angular, &c. It may be described as follows:—The skin is first rendered perfectly pure by previous washing with a 1-20 carbolic lotion, and any hair or down removed, the razor being carried for a short distance into the temporal region. The auditory meatus and external ear are purified thoroughly, and the former plugged with a piece of salicylic wool or cyanide gauze. The skin incision is so planned as to leave a scar as unobtrusive as possible. Commencing about the middle of the zygoma, the knife is carried backwards and downwards over the parotid region to the angle of the jaw, and then for a short distance along the horizontal ramus. A semilunar flap consisting of skin and subcutaneous tissue only should be raised and turned forwards, and for convenience temporarily stitched across the opposite side. This flap must be carefully dissected up so as not to injure any of the branches of the facial nerve. By this means are exposed the masseteric fascia, the branches of the facial nerve passing across Stenson's duct and a portion of the parotid gland. The deep fascia and masseter muscle are then divided by a transverse incision below and parallel to Stenson's duct, cutting directly down to the bone about a centimetre below the sigmoid notch. Great care must be taken not to wound any lobules of the parotid in so doing, for even though the main duct be not divided a salivary fistula may ensue, leading to interference with the healing of the wound. The outer surface of the jaw is next denuded of periosteum by means of raspatories, and the soft parts held aside by suitable retractors to allow of the application of a trephine, the diameter of which should not be less than three-quarters of an inch. It should be so applied as to leave between it and the sigmoid notch a narrow bridge of bone which can be subsequently clipped away by cutting pliers, and a sufficient thickness of bone in front and behind to preserve the continuity of the jaw with the articular and coronoid processes. Great care should be exercised in consequence of the varying thickness of the bone, the lower part being thicker than the upper; otherwise the inferior dental artery may be cut through by the trephine and give rise to troublesome hæmorrhage at a time when it would be extremely inconvenient. The disc of bone having been lifted out and the bridge of bone between the condyle and coronoid process clipped through with bone pliers, some loose fatty tissue presents and should be carefully picked away with two pairs of dissecting forceps. The tendon of the temporal muscle is thus more clearly defined, and must be held forwards if necessary. Narrow spatulæ are useful at this stage, not only to keep the wound open, but also by their pressure to arrest hæmorrhage from divided muscular branches. If the bleeding is troublesome the wound should be packed for a few moments with small pieces of sponge wrung out of hot 1 in 40 carbolic lotion, any obvious bleeding point being secured by ligature. The inferior dental artery is usually first seen, and may be secured by passing two ligatures around it with an aneurysm needle and dividing it between them. The lowest fibres of the external pterygoid muscle are seen running transversely across the wound, and require to be held upwards or carefully divided, to demonstrate the two nerves passing down from behind it. The trunk of the inferior dental nerve can then be raised upon an aneurysm needle, and the lingual found a little internal and in front of it. It occasionally happens that the nerves lie in such close proximity to one another that they are picked up together. It is advantageous to pass a silk or catgut ligature around them in order to be able to make traction upon them. It is now easy by a little manipulation with the handle of a scalpel to separate them right up to the foramen ovale, which can even be seen if the external pterygoid muscle be held out of the way. The nerves can then be divided close to the skull either by scissors or knife, and the meningeal artery should be in no danger if the nerves have been carefully isolated. Peripheral traction is also employed so as to draw up as much of the nerve as is possible, and thus a considerable portion—more than an inch—of the trunks can be readily removed. All bleeding having been arrested, the wound is carefully irrigated with some 1 in 40 carbolic lotion, and the skin flap neatly brought together with a continuous suture. There is no need to insert a drainage-tube, and as a rule healing by first intention is readily obtained. I have performed this operation repeatedly during the last seven or eight years, with comparative ease, with relief to the patient for the time being, but I must also confess that in by far the majority of the cases the pain recurred at the end of a year or two, necessitating those further measures which I shall detail in my next lecture."

(This lecture, like the former, was illustrated by diagrams representing the position of the different divisions of the nerve, and by drawings of the different operative measures alluded to.)

Clinical Lectures
ON
STRICTURE OF THE ŒSOPHAGUS,
WITH FOURTEEN ILLUSTRATIVE CASES, IN FOUR OF WHICH GASTROSTOMY WAS SUCCESSFULLY PERFORMED.

BY DAVID NEWMAN, M.D.,
SURGEON TO THE DEPARTMENT FOR DISEASES OF THE THROAT AND NOSE AT THE ROYAL INFIRMARY, AND ASSISTANT SURGEON TO THE WESTERN INFIRMARY, GLASGOW; PRESIDENT OF THE GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

LECTURE II.

GENTLEMEN,—In the last lecture I discussed with you fully, and illustrated to you by cases, the most common and therefore most important variety of œsophageal obstruction—namely, carcinomatous disease. To-day I will merely allude to sarcoma of the œsophagus, make a few remarks regarding benign tumours, then consider cicatricial stricture, and, subsequently, the general question of prognosis. Sarcomatous disease of the œsophagus is very seldom met with as a primary lesion, but frequently the gullet becomes implicated secondarily. This is most commonly observed in sarcoma of the lungs, mediastinal or cervical glands, thyroid gland, larynx, and of the vertebræ. Rosenbach has reported a case in which a soft, transparent, and lobulated tumour about the size of a hen's egg was attached to the upper end of the œsophagus on the right side, and which, on microscopic examination proved to be a small round-celled sarcoma. A case is also recorded by Dr. Chapman[1] and another by Dr. Lauriston Shaw.[2] In the latter case the sarcoma appeared as an ulcer with well-defined margins, and, destroying an extensive area of the mucous membrane of the gullet, eventually it perforated the posterior wall of the trachea just above the bifurcation.

Benign tumours of the œsophagus are very seldom met with in practice. It is a remarkable fact, and one not easily explained, that while the pharynx, larynx, and posterior nares are all liable to be occupied by non-malignant neoplasms, the gullet very seldom is. Indeed, benign tumours are so seldom seen in the latter situation that I do not purpose to occupy time by referring to the cases which have been recorded further than to say that cases of papillomata, cysts, fibromata, adenomata, and lipomata have been published as curiosities, and I have in this jar a remarkable example of a very large myoma of the gullet. This tumour, as exhibited in the preparation, is situated in the lower part of the œsophagus, its inferior extremity just reaching the cardiac orifice of the stomach. The tumour measures four inches and three-quarters from above downwards, one inch to one inch and a quarter from before backwards, and on an average about two inches laterally. It lies mostly free, but is attached to the posterior wall of the passage by a very thin fibrous band about an inch and three-quarters in length, and with its upper edge about two inches beneath the superior margin of the tumour. The œsophagus, at the

[2] THE LANCET, March 21st, 1891, p. 660.

Digitized by Google

part occupied by the tumour, was much dilated, and its mucous membrane presented considerable ulceration. On microscopic examination the tissue was found to be composed of elongated spindle-shaped cells presenting the character of the smooth muscular fibre cell. The tumour was thus concluded to be a myoma or muscular tumour. With the exception of the œsophagus, all the organs of the body were normal. During life the patient, who was under the late Dr. Steven in ward 5, complained chiefly of difficulty and pain in swallowing, which, as he stated, were first experienced about two months before death. There was no actual vomiting, but when an attempt was made to swallow, the food soon regurgitated. During his stay of two months in the hospital, examination with the bougie detected an obstruction in the œsophagus. The patient, who on admission had a good complexion and was not emaciated, began after a fortnight's residence to lose flesh rapidly, till at death he was extremely emaciated.[3] Again, this other specimen, also from the museum, is an example of a simple papilloma of the œsophagus. The tumour is situated on the anterior wall of the gullet, immediately behind the cricoid cartilage, and only involves the superficial structures of the mucous membrane. During life it caused considerable obstruction to swallowing, although it is not larger than half a grape. The patient died of Bright's disease, but for a short time before death he was unable to swallow solid food, and even fluids passed with difficulty.

The diagnosis of benign tumours, unless when they are so high up as to be visible, is by no means easy. The slow development of symptoms, the absence of pain, and no involvement of the lymphatic glands, distinguish benign from malignant neoplasms, and the history of the case in respect to injury usually prevents traumatic stricture from being overlooked. When the tumour is situated high up, as in the specimen of papilloma I have just shown you, dysphagia develops rapidly; while if the growth is situated low down, as in cases of myoma, a compensatory dilatation of the gullet may occur, so that food passes, even although the tumour may have attained an enormous size.

The next form of obstruction which falls for our consideration is cicatricial stricture of the gullet. The etiology of this form of stricture is fully demonstrated by the specimens and cases which you have seen. When the mucous membrane is injured in any way, either by a wound or by the action of severe inflammation, the abraded surface separates, and granulation tissue fills the vacant space; and, as a consequence of the development of the round-celled into more highly developed tissue, contraction takes place, and the lumen of the gullet is diminished. I have here a specimen which was removed from the subject of a very distressing group of cases. Three children were left by their mother, and on the table of the house a cream jug was placed, the contents of which the young ones proceeded to divide amongst themselves, believing that it contained cream. Their ages were three, five, and ten years respectively. They divided the contents of the jug equally, and all drank it at the same time. Instead of being cream, the contents of the vessel were a mixture of sulphuric acid and ground pumice-stone used for cleaning brass. The youngest child died, but the two others recovered.[4] This preparation shows you the destructive action of the poison. I may say that when the patient was admitted the mucous membrane of the inside of the lips, dorsum of the tongue, and palate had a white appearance, as if burned by a corrosive acid, and the patient was vomiting a thick tarry-looking substance, which had a strong acid reaction. The peritoneal cavity contained several ounces of fluid, which had the appearance of a mixture of chocolate and milk, and was devoid of fæcal odour. The peritoneum also contained a quantity of gas. The stomach had been completely charred and thrown into large irregular folds, and when the slough was removed an eroded and bleeding surface was exposed. The duodenum contained a quantity of coffee-like fluid, but there was no destruction of its mucous membrane. The two other children recovered from the immediate effects of the poison, but subsequently they suffered from stricture of the œsophagus. To these cases I shall refer when speaking of treatment.

[3] The full account of this case is recorded by Dr. Joseph Coats in the Glasgow Medical Journal for February, 1872.

[4] The patients were in the first instance admitted into Dr. Wood Smith's ward, and I treated the two eldest for cicatricial stricture afterwards.

During this session you have had brought under your notice at the demonstrations four cases of cicatricial stricture, and in all of these the contraction has been caused by injury from swallowing chemicals or hot fluids. When the injury is severe or the poison concentrated, the gullet and stomach may be so destroyed that death results within a few hours. You have here two specimens of sulphuric acid and one of nitric acid poisoning. In the first two mentioned cases the acid was taken in considerable quantity and in a concentrated form, so that the œsophagus is denuded of its epithelium, and the longitudinal muscular fasciculi are exposed. In both cases death occurred within twenty-four hours. When, however, the injury is less extensive or severe, an acute œsophagitis follows, the destroyed mucous membrane becomes replaced by granulation tissue, and, as healing progresses, the cicatricial tissue contracts. The extent of the stricture depends upon the primary injury. Contraction takes place slowly, so that the usual history of the case is that while the patient suffers severe pain, and experiences great difficulty in swallowing immediately after the accident, within a few days relief comes, and he is able to swallow food easily for weeks. Then the granulation tissue begins to contract, and the patient complains of steadily increasing dysphagia. The stricture may only occupy a small area of the gullet, as in this specimen. Here a portion of the œsophagus is laid open, and a stricture is seen at its centre, where the muscular fibres are very much contracted. The stricture is caused by cicatricial contraction extending through a small area of the long axis of the œsophagus, the contracted portion not including more than a quarter of an inch of the length of the gullet. The walls are normal both above and below the stricture. In other cases the contraction may extend throughout the entire length of the tube, or there may be several smaller strictures. In all cases of cicatricial stenosis of the œsophagus, the most pronounced and characteristic symptom is difficulty in swallowing, but it must be remembered that the closeness of the stricture cannot always be judged by the amount of dysphagia. Not uncommonly, as in the cases of G. R—— and D. McA——, whom you saw at the beginning of the session, the organic stricture is accompanied by spasm.

CASE 10.—G. R——, aged thirty-one, was first seen by me in September, 1889, and since then he has been coming to the ward regularly to have a bougie passed. The history of the case is very simple and short. About two months previous to admission—that is to say, in the middle of July, 1889—he swallowed, by mistake for cream, a tablespoonful of a mixture of caustic soda and lime used for cleaning brass. Immediately after swallowing this he was seized with a severe pain in the mouth, throat, and stomach, and at once vomited the contents of the stomach. For the first fortnight he suffered from the ordinary symptoms of acute inflammation of the œsophagus and mouth — namely, painful dysphagia, dyspnœa, and expectoration of blood-stained mucus and shreds of mucous membrane. When admitted to hospital the pain was relieved somewhat, although still occasionally present in a paroxysmal form. At this time it was found almost impossible to pass a bougie, partly on account of the suffering which it caused the patient, and partly by reason of spasm induced by the presence of the instrument. For some time he had to be nourished by rectal injections, but after a fortnight's rest to the œsophagus I succeeded in introducing a small-sized bougie (No. 6), and from that time till now (March, 1891) he has had instruments passed at regular intervals, and he is thereby enabled to take a good quantity of solid and fluid food; he has gained his normal weight, and follows his occupation. In this case the obstruction includes the whole or nearly the whole length of the gullet, so that in introducing an instrument no localised stricture is detected, but if the patient fails to have a bougie introduced, say, for a fortnight, he is soon reminded of his condition by finding that he is unable to swallow solid food.

In another case which you have seen this session the stricture, although caused in much the same way, is very limited in extent.

CASE 11.—G. T——, aged forty-nine, was admitted into the Royal Infirmary on Sept. 10th, 1890. Eight months previous to admission he swallowed a small quantity of caustic soda solution, which was vomited immediately, but nevertheless he suffered soon after from a very acute attack of œsophagitis, and from that time till admission dysphagia steadily increased; so that when he came before you for the first time he could only take fluid or semi-fluid food. On

Digitized by Google

introducing a bougie a distinct and well-defined stricture could be made out at the level of the bifurcation of the trachea. The treatment resorted to was gradual dilatation, which has been so successful that by the end of the year the patient only required an instrument passed once a month in order to enable him to swallow with perfect ease.

CASE 12.—The last case of well-defined organic stricture of the œsophagus you saw was D. McA——, aged fifty-one. He was admitted to the ward on Jan. 20th, 1891, complaining of great difficulty in swallowing, of seven weeks' duration. He states that seven weeks previous to admission he swallowed by mistake for whisky a burning liquid said to be vitriol. Indeed he had been in the habit, as a railway porter, of seeking for whisky in "returned empties," and on that particular occasion he failed to distinguish the nature of the contents of the jar until it had burned his throat, tongue, and mouth so severely that, as he says, "a skin peeled off those parts." Immediately on finding out his mistake he swallowed a large quantity of cold water, which was at once vomited, and he describes the vomited matter as being very acid in taste and consisting of "phlegm and a skin." For a fortnight after the accident he suffered from acute inflammation of the mouth and œsophagus, and the only food he took was milk and soda-water. On admission he was able to take semolina and milk, but was quite unable to swallow any solid food. On passing a bougie a long narrow stricture was found, extending from the level of the cricoid cartilage to the bifurcation of the trachea. The introduction even of a small instrument was attended with great pain and spasm. The patient was therefore fed exclusively per rectum for ten days, no food being given by the mouth, and no instruments were introduced during that time. After rest for these ten days a successful attempt was made to pass a No. 8 bougie, and two days thereafter a No. 9 was easily introduced, and so on; every second day a larger size was passed until a No. 17 was got through the stenosis. By this time the patient was able to take solid food with freedom, and was soon after dismissed, but he still comes to the hospital once a week to have a bougie introduced.

(To be concluded.)

THE BEARING OF RECENT BIOLOGICAL RESEARCHES ON THE PRACTICE OF MEDICINE AND SURGERY.

BY G. SIMS WOODHEAD, M.D., F.R.C.P.EDIN.,
DIRECTOR OF THE LABORATORIES OF THE ROYAL COLLEGES OF PHYSICIANS (LOND.) AND SURGEONS (ENG.).

(Continued from page 131.)

IT has often been suspected that bacteria from imperfectly sterilised skin surrounding a wound which an attempt has been made to keep aseptic were accountable for the putrefactive and septic changes that are specially prone to occur in wounds of certain parts of the body. Lister and Watson Cheyne have both insisted that this may occur, and other surgeons have arrived at the same conclusion. So important has this question become that Geppert and several workers in the Johns Hopkins University pathological laboratories have paid considerable attention to the methods of sterilisation not only of the hands of the operator, but of the skin surrounding any incision or wound. I have also carried out a number of experiments with the view of determining how far the various methods of sterilising the skin are efficacious.

Let us consider the enormous number of micro-organisms that have been described as occurring in the skin; Eisenberg[1] describes about thirty; whilst, counting all those that have been described by various observers, the number amounts to something over one hundred. These organisms have been found in and beneath the dead epithelium, around the hairs, and, more important still, embedded in the fatty material of the sebaceous ducts and follicles, and it is often a matter of the very greatest difficulty to wash away even a small quantity of the organism-holding substances. It is a matter for little wonder, therefore, that with merely ordinary precautions suppurating points should occur where stitches have been introduced, or even at the lips of the larger wound itself. Many of these organisms, of course, have little or no effect in producing suppuration; but, as we learn from those who are specially interested in the study of skin diseases, the staphylococcus pyogenes albus and the staphylococcus pyogenes aureus and certain other pus-producing organisms are very frequently met with in the skin, and under certain conditions play a very important part in the production of pustular eruptions. I myself have frequently separated from the cloudy serum of herpes vesicles both of the above forms; whilst only the other day I was told by Dr. Eddowes that previous to the examination of a patient suffering from an impetiginous eczema he had wrenched one of his nails slightly from the matrix. He examined the patient, washed his hands carefully, but took no special antiseptic precautions, with the result that a small abscess formed very rapidly, from which he obtained an almost pure culture of staphylococcus pyogenes aureus. These organisms, then, present in the skin may be the cause of some of the unexplained suppurations that now and again occur. I should here like to point out that even this danger may be guarded against by the use, first of all, of a liberal application of soap and warm water, followed by a good scrubbing with a mixture of alcohol and ether, and then by the use of some ethereal antiseptic before the operation is begun.[2]

As yet, however, there is not a practical method of keeping the skin perfectly aseptic for any lengthened time, and for this reason any method of dressing that allows of free evaporation of moisture from the cutaneous surface will probably give better results, in some cases at any rate, than where the moisture is kept in and has to pass over a considerable surface before it comes in contact with the atmosphere. Welch[3] and Halsted maintain that many of the small stitch suppurations are due not to tension, but rather to the presence of a staphylococcus, which they speak of as the staphylococcus epidermidis albus, which is very frequently present in the skin, an organism which is assumed to be very like, though probably not identical with, the staphylococcus pyogenes albus; there can be little doubt that in some cases at least this or some similar organism is accountable for the suppuration that is set up.

On the other hand, Surgeon W. Grant Macpherson, A.M.D., in a series of experiments carried on with what were supplied as aseptic sutures, has shown that even in the hands of the best instrument makers aseptic sutures contain various micro-organisms, and he maintains that the organisms in these sutures may in some cases be accountable for the small stitch abscesses that occur around wounds. So frequently has this occurred that some surgeons have recommended the use of deep sutures, first of all to take the strain off the superficial stitches, and more recently because it was thought that the abscesses were due to the presence of pyogenic organisms in the skin around the sutures, along which, as the distance was short, the organisms could readily pass to the main wound. Of course it is only in exceptional cases that we have to deal with such points; but the exceptional cases are those which present most difficulty, often taxing to the utmost the skill and ingenuity of the surgeon; and the more these exceptional cases can be brought under general rules for treatment, the greater will be the improvement in surgical treatment, and especially in conservative surgery.

I have already spoken of the invasion of the blood and of the tissue by micro-organisms from the alimentary canal and from the respiratory tract. As there are as many organisms described in these positions as on the skin, it is not to be wondered at that surgeons have often suspected the entrance of organisms into their wounds by these tracts. There have been at least one hundred organisms described by different observers

[1] Bakteriologisch-Dignostik. Hamburg and Leipzig, 1891.

[2] The want of knowledge of the difficulty that is involved in this cleansing of the skin has on several occasions led to very erroneous conclusions, especially where attempts have been made to isolate the organisms associated with special diseases, the mistakes made in two series of observations (at least) depending on imperfect cleansing of the skin where it has been necessary to obtain blood or fluid through punctures of the skin, and we are compelled to come to the conclusion that some of the so-called scarlatina and leprosy bacilli are nothing more than forms of bacteria that are frequently found in the skin under perfectly normal conditions.

[3] Loc. cit

Digitized by Google

as being found at some time or another in the mouth alone, whilst others have been found under different conditions in different parts of the alimentary canal and in the lungs. So important a part do they play that it is now maintained that the ring of lymphoid tissue at the upper end of the pharynx, the most highly developed part of which is the pharyngeal tonsil, is placed specially to act as a kind of defensive outwork to prevent the entrance of a large number of micro-organisms that are present in the mouth; whilst it is further maintained that the lymphoid tissue so universally present throughout the alimentary tract is placed there for a similar purpose. Whilst these are acting normally no micro-organisms can make their way into the tissues, but once this tissue is removed, or by disease is rendered incapable of doing its work, the entrance of micro-organisms is allowed, and if the tissues are below par, or if there are dead tissues at any point in the body, an abscess may be the result. To indicate the importance of this, "the first line of defence," one has only to recall cases resulting from necrosis or suppuration of the pharyngeal glandular tissue in scarlet fever, diphtheria, and similar diseases, conditions which are often followed either by acute septic poisoning or by regular pyæmic conditions; or those cases of enteric inflammation where there is destruction of the lymphoid tissues—a condition which is so frequently followed by similar septic and pyæmic conditions. It may be accepted as a general rule that in no surgical cases should bacteria or their products be allowed to remain unchanged for any length of time in the alimentary canal. The older surgeons had great belief in the use of purgatives; it was said that purging was an antiphlogistic treatment, and so it is. Not only are the effete products of the body removed, but the bacteria and their products which flourish in this effete matter are also got rid of by judicious purgation. On the other hand, it must be remembered that any over-stimulation of the intestine exhausts the cells and so weakens them as defensive agents. Whilst on this subject, though it properly comes in under the next heading, it may be pointed out that the maintenance of the excretory organs in good working conditions is one of the most important elements in the success of antiseptic surgical treatment. Even from the point of view of the most ardent believer in phagocytosis this will be admitted; whilst those who believe in the microbicidal action of the fluid elements of the serum will be equally ready to accept it. Not only do the effete substances of the tissues, if retained for any length of time, exert a poisonous action on the tissues themselves, but all poisonous products of certain bacteria formed within the body, and certain poisonous substances taken into the body from without, are all excreted in the same manner; for instance, if cholera poison is injected subcutaneously or intravenously, hæmorrhages will be found to occur in parts of the alimentary tract; whilst following the exhibition of other poisons, although no regular hæmorrhages occur, intense congestion is found, and the poisonous substance is found in the alimentary canal, showing that in both cases an effort has been made on the part of the organism to get rid of the poison by the ordinary excretory channels. This being the case, it is of the very greatest importance that the intestinal tract especially should be kept free from accumulations of effete matter: first, in order that such matter may not be reabsorbed; and secondly, to allow of a free passage outwards of any substance which may interfere (a) with the free action of the leucocytes and of the other cellular tissues, and (b) with the normal constitution of the fluids of the body.[4]

The third factor in antiseptic surgery is the cultivation of the *vis medicatrix naturæ* by which the tissues are to be placed under the best possible conditions, so that the phagocytes or the blood serum may exert, to the full, their special protecting powers. As is well known, anæmia (where the quantity of blood is small, or the blood is vitiated) may be a powerful factor, indirectly, in the production of pyæmic and septic processes, and any method of preventing the loss of blood, short of depriving the tissues of their blood-supply for lengthened periods, is of direct assistance to the surgeon who wishes to keep his wounds aseptic. Similarly, good ventilation acts not only directly in interfering with the growth of pathogenic or pyogenic organisms from wards, but also by improving the general health of the patient; whilst good nutrition and efficient excretion, as already mentioned, play an equally important part in maintaining the resistant powers of the tissues or of the cells of which they are composed. There can be no doubt that this element of tissue nutrition had been early grasped; and Sir James Paget, from his enormous experience and keen observation, came to the conclusion thirty years ago that septicæmic patients treated in the open air, in tents, stood a far better chance of recovery than those treated under ordinary conditions; whilst in our own time physicians who have ordered their patients suffering from phthisis to live out in the open air as much as possible—as, for instance, in Egypt, or camping out in the Adirondack—have obtained better results than by any other method of treatment. In all cases the object is so far to nourish and strengthen the tissues that they are able to carry on their functions, to destroy and eliminate invading organisms and their poisons, and under stimulation to form new organising tissues instead of undergoing retrogressive and degenerative changes.

Lastly, in antiseptic surgery it is necessary to remove and keep from the region of the patient, from dressings, from the instruments used—in fact, from everything which may come in contact with the wounded tissues, from the hands of the surgeon downward—all organic and other matter which might possibly harbour putrefactive or septic germs. The first end may be obtained by thorough cleanliness and the use of hot water and alkalies, either in the form of soaps or lyes, to get rid of all fatty or other organic matter which may have accumulated. (It must be remembered, however, that where blood or other albuminoid substance is present careful washing with cold water will be much more effective than when hot water is used.) It is a somewhat difficult matter to apply moist heat to instruments because of the difficulty of preventing rust in the presence of moist air maintained at a high temperature; whilst, on the other hand, if dry heat be employed, a temperature of 150° C. is necessary for the destruction of spores in the dry condition, and this plays such havoc with the handles of instruments that even those who have appreciated its other advantages have been compelled to relinquish its use. Now, however, many sterilisers, in which steam is used for this purpose, have been perfected.[5] The greatest attention should also be paid to the cleansing and disinfecting of the hands of the surgeon, and here it may be pointed out that any amount of washing with chemical antiseptics cannot take the place of soap and water and other material used for the removal of dead epithelium and sebaceous or other fatty material, both of which, as we have seen, form such a favourable nidus for the harbouring and development of micro-organisms. As regards ligatures and sutures, from observation of a large number of experiments carried on by Surgeon Macpherson, I am satisfied that many of the so-called aseptic ligatures are thoroughly unreliable, and that such a substance as silk, for instance, is a better ligature before it has been treated by special methods than afterwards, from the simple fact that the men who use perfectly good methods of sterilisation do not understand the object to be attained, and therefore introduce some slight modification or manipulation of their own which vitiates the whole process. I agree, therefore, with those surgeons who hold that, in order to obtain good results, ligatures should be prepared under the supervision of the surgeon himself or of someone in whom he has the utmost confidence. It is for this reason that those who use boiled silk or pure silk direct from the hands of the manufacturers by whom the fibre has been submitted to the action of most powerful chemical substances, such as acids, chlorine, &c., often obtain better results than where special antiseptic substances have been used. As regards sponges, the difficulty of getting nurses and dressers to pay strict attention to the directions given for sterilising and keeping

[4] It was supposed at one time that these hæmorrhages found in cases of acute poisoning were due to the direct action of the poison on the mucous membrane as it passed from the stomach and along the alimentary canal, but it has now been proved that these poisonous substances are frequently absorbed in the first part of the alimentary canal, and that they are again excreted lower down, where they give rise to the conditions above described.

[5] Of all those I have seen tried, the most convenient and at the same time one of the best and most economical is that devised by Mr. C. W. Cathcart, F.R.C.S., of Edinburgh. Instruments cleansed and heated therein and then placed in a tray containing weak carbolic acid solution may be used without fear of their bringing any contamination to the wound.

Digitized by Google

them sterile are so great that I believe the plan now adopted by many surgeons of using pledgets of cotton wadding which have been wrapped up in paper and subjected to a dry temperature of 150° C., and then wrung out in dilute antiseptic solution, is preferable to any other that has been suggested.

When we come to the consideration of the dressing of the wounds and of keeping the surroundings of the wound aseptic during operation, another factor enters into our calculations; a dressing must be aseptic in order that nothing coming in contact with the wound may introduce septic material, but to be a perfect dressing it must also be permeated with a quantity of an antiseptic substance sufficient to saturate the fluids which come from the wound through the dressing, and to render these albuminous fluids when they arrive at the surface incapable of serving as nutrient media for the growth of organisms. For this reason, and from experience of a considerable number of cases both in wards and in experimental work, I am satisfied that the very best results are obtained where the following points are attended to—viz., a dressing should be as absorbent as possible; all material used in its manufacture should be thoroughly sterilised; it should then be impregnated with a soluble antiseptic; it should be of sufficient thickness to absorb in its deeper layers all fluid discharge; and it should be changed or added to whenever the discharge comes near the superficial layers. Evaporation should be allowed to go on freely from the outer surface in in order that the moisture, without which organisms are placed at a great disadvantage both as regards development and power of movement and facilities for transportation, may be carried off, in order that the conditions of healing under the scab may be approached as nearly as possible under these artificial conditions. It is, at this date, scarcely necessary to point out that everything around the patient during an operation should be perfectly aseptic, and should be so saturated with antiseptics that when an instrument is laid down it will not be contaminated, and that anything settling thereon shall not only be acted on by the antiseptic, but shall be prevented from making fresh excursions during which it might possibly reach the wound. If these points are attended to, flushings and sprays may be of little additional use; but we must bear in mind that both these agents help in no small degree to the keeping up of those antiseptic surroundings which are so important a feature in the successful treatment of wounds. Of course it has been objected, and will be objected, that many surgeons are able to obtain a large proportion of successful results without the use of antiseptics; some even maintain that antiseptics do more harm by their presence in the tissues than they do good outside; and so they may when not properly used, though against those who understand the principles of antiseptic surgery this is a reproach that can never be substantiated. Those who disavow antiseptic surgery frequently use, without exception, one of the most potent antiseptic agents that we have at our command—heat; they heat their instruments most carefully, and many of them boil the water used for cleansing and flushing purposes. They are also impressed with the necessity there is for cleanliness, for very fortunately no school of surgery can claim a monopoly of this; the only claim that antiseptic surgery can make on this head being that it makes a demand for a more detailed cleanliness than does any other school. As regards damaging the tissues and interfering with their antiseptic powers, many of our brilliant operators who do not believe in antiseptic surgery, undoubtedly reduce this to a minimum, and thus in comparatively healthy operation cases obtain favourable results, and with less suppuration than where antiseptic substances are introduced into the wound, irritating the tissues and impairing their vitality. There is no system of aseptic surgery which is not based on the use of antiseptics in some form or other, and the more completely we recognise this principle, however we may have to modify the methods and detail (discarding the term aseptic as too narrow and incomplete), the more satisfactory will be the results obtained.

(To be continued.)

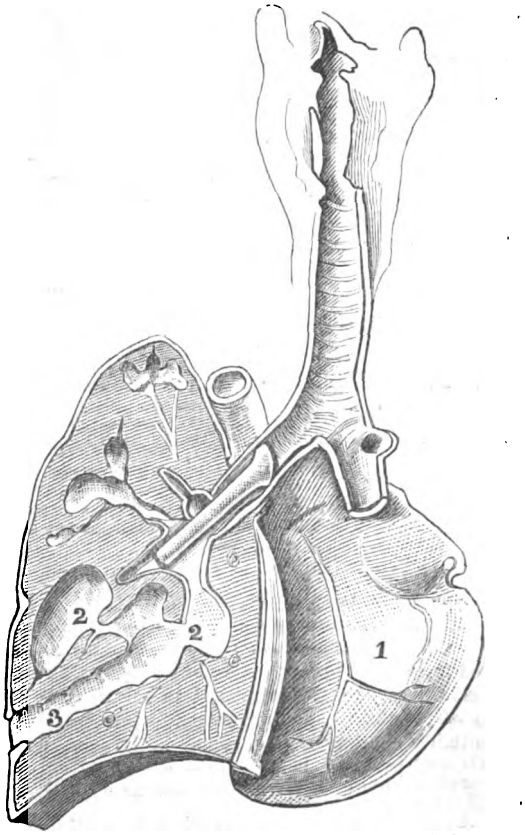
WELLINGTON COLLEGE.—Owing to the present insanitary condition of Wellington College the next term will be carried on at Ilfracombe, where it is contemplated to secure two large hotels for the accommodation of the staff and students.

CASE OF A BRONCHIECTATIC ABSCESS DUE TO THE IMPACTION OF AN O'DWYER'S TUBE.

BY G. A. SUTHERLAND, M.A., M.B. ED., M.R.C.P.L.,
PHYSICIAN TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION; REGISTRAR AND CLINICAL ASSISTANT, PADDINGTON-GREEN CHILDREN'S HOSPITAL.

AT the end of March, 1891, P. P——, male, aged seventeen years and a half, came to me with the following history. On the previous day he had been walking behind a van which tilted over on one side owing to a wheel getting into a rut, and a projecting piece of wood struck him on the front of the neck and the under surface of the chin. He had had pain in the throat since and some difficulty in swallowing. There was a small cut through the skin over the lower surface of the symphysis menti, but no other mark of injury. A week later the pain was more severe, and was referred to the region of the thyroid cartilage. There was tenderness on pressure over this area, and the voice was husky. The temperature was 101°, and a cough had set in accompanied by mucoid expectoration. A week later he was much worse. The breathing was loud, quite audible across the room, and was evidently due to some tracheal obstruction; a slight laryngeal stridor was also present. At times there were suffocative attacks, especially during the night. The temperature continued between 101° and 102°; the cough was frequent, of a very exhausting type, and there was expectoration of frothy mucus in large quantity. Sweating was frequent. There was nothing abnormal found in the lungs, heart, or other organs. He was sent to a general hospital, where laryngotomy was performed on the morning after admission, with partial relief to the dyspnœa. His condition remained very critical for some weeks, but eventually the laryngotomy tube was removed, and intubation of the larynx was employed for the relief of stenosis, which had supervened. During a fit of coughing the string attached to the tube broke, and the tube passed down into the trachea. Several efforts were made to remove it, but unsuccessfully, and he became an out-patient at the end of July.

On August 14th he came to me again. He had been at the seaside for ten days, had put on flesh rapidly, and was looking strong and robust. The breathing was loud, of a combined laryngeal and tracheal type, quite audible across the room, and louder after exertion or coughing. The voice was very husky. He had a frequent cough, accompanied by expectoration of pure pus, sometimes amounting to fifteen ounces per diem, not offensive, and in which no tubercle bacilli could be found. Laryngoscopic examination showed marked narrowing in the region of both the false and the true vocal cords, the latter forming a small oval aperture which did not increase or diminish in size during respiration. The anterior end of the opening lay rather to the left of the middle line. As regards the chest, the respiration was regular and easy; expansion was equal and good on both sides; the note was hyper-resonant all over; the breathing was loud blowing, evidently conducted from the upper air passages, and more marked on the right side; and a few scattered râles were occasionally heard. The only evidences of acute mischief were the coughing, which was at times accompanied by attacks of dyspnœa, and the profuse expectoration of pus. Apart from these, he expressed himself as being in the best of health, and was out in the open air the whole day when the weather was favourable.



On my return to town on Sept. 23rd, I found him to be much worse, and obtained the following history: Until fourteen days ago he had continued very well, when he was seized at night with a violent fit of coughing which lasted three hours. During this attack he felt something move in his chest, and the breathing suddenly became quiet. He had not been out of bed since, and had lost flesh rapidly. The cough had been more constant, with profuse purulent expectoration, sweating, and sometimes sickness. The decubitus was entirely dorsal. If he sat up or lay on his right side violent continuous coughing set in; if he lay on the left side, he felt as if his heart were stopping. The breathing was very much quieter, with the tracheal

Digitized by Google

element quite gone, and, after coughing, rather wheezing in type. The voice was husky as before. The temperature was 102°, and there was much sweating at night. There was some flattening and drawing in of the left side of the chest, specially marked in the axilla, and expansion was very much diminished on the same side. He stated that he had felt something move in his chest on the left side, slightly to the left of the sternum and about three inches from its lower end. He had pain occasionally in the same spot still. There was a distinct wave of pulsation over the whole cardiac area with each beat, and the apex was felt in the fourth intercostal space, just outside the nipple. Over the whole of the left side of the chest there was dulness, well marked, with bronchial breathing which was most intense over the upper lobe, No accompaniments were heard, and vocal resonance was slightly increased. The right lung was hyper-resonant on percussion, and the breathing was harsh vesicular, with occasional rhonchi. The general symptoms continued, and further examination of the chest showed loud blowing breathing at the inferior angle of the left scapula, with metallic râles and whispering pectoriloquy. Dr. Leonard Guthrie kindly saw the case, and diagnosed a bronchiectatic cavity in the lower lobe of the left lung. The expectoration was intermittent; at times a large quantity of pus would be brought up with severe paroxysms of coughing, and there would be a cessation of both expectoration and cough for some hours. He continued to lose flesh and strength. The expectoration at times was very fetid; the temperature was very irregular, often up to 101·4°; and operation was decided on. As he absolutely refused to go into hospital, Mr. H. L. Lack kindly undertook to operate at the patient's house. On Oct. 10th, the patient being under chloroform, Mr. Lack resected three inches of the sixth rib on the left side in the axillary region. On opening the pleura a very small quantity of clear fluid escaped; the lung was very collapsed, and there were no pleural adhesions around the opening. It was resolved accordingly to wait until adhesions had formed. On the 19th the patient was again chloroformed, and Mr. Lack proceeded to explore the lung. Having made a small slit through the visceral pleura, he introduced an aspirating needle in different directions. On passing it backwards some offensive pus was obtained, and on enlarging this opening he was able to introduce his finger into an abscess cavity. It seemed to pass backwards and upwards, but extended beyond reach of the finger. No foreign body could be felt with the finger or probe. The cavity was packed with cyanide gauze, as was also the pleura around the wound, the recent adhesions having given way under manipulation. There was very little bleeding, and the patient stood the operation well. On the first dressing, a large drainage-tube, four inches long, was introduced into the abscess cavity. The temperature improved after the operation, and remained under 100°. The drainage was good, and the expectoration and cough were very much lessened. Mr. Lack again examined for a foreign body in the lung, but failed to find any. On the 30th there was some hæmorrhage into the dressing, and the cough was more troublesome owing to a bronchitic attack. There was very severe hæmorrhage from the lung on removing the drainage-tube three days later; and on Nov. 7th, while he was lying quietly in bed, the bleeding recurred, and proved fatal almost immediately.

A post-mortem examination was made on the following day. There was marked stenosis of the glottis, with congestion all along the trachea, but no marks of injury or abscess apart from the cicatricial tissue at the site of the laryngotomy wound. The right lung was much hypertrophied, somewhat emphysematous, and passed well over to the left of the middle line. On the left side there were pleuritic adhesions round the lung, very firm around the upper lobe and the base of the lower. The left lung was very small and dark in colour. On opening the left bronchus an O'Dwyer's tube was found (size No. 3, length two inches and a quarter), the head lying three-quarters of an inch below the bifurcation of the trachea, and the body passing down into the bronchus leading to the lower lobe. On passing a finger into the operation wound, it entered directly a large cavity in the lower lobe, and touched at the upper part the inferior extremity of the O'Dwyer's tube. The greater part of the lower lobe was destroyed by the abscess, and the part remaining was collapsed and airless. The abscess was smooth at the upper part, the wall of which was formed of the dilated bronchus, and soft and irregular in the lower part; the smaller bronchi around were dilated and surrounded by soft and easily broken-down lung tissue. The tube was lying free in the bronchus; and on removal it was seen that the head had eroded through the bronchial wall, and was separated from the pulmonary artery by a thin layer of fibrous tissue. The left upper lobe was collapsed and solid. The bronchus leading to it was blocked by the side of the tube, which lay immediately over it, and the smaller bronchi were dilated. The abscess cavity and upper air passages were filled with blood, but the exact site of the hæmorrhage could not be determined. The other organs presented no special points of interest.

On looking at the above case in the light of the post-mortem evidence some of the difficulties are cleared up, but others still remain. The original injury, trifling to all appearance, was followed by pharyngitis, laryngitis, and tracheitis, accompanied by cough, dyspnœa, and profuse mucoid expectoration. What was the lesion? On surgical examination, nothing abnormal was found about the region

Vertical transverse section of left lung, viewed posteriorly, showing the tube *in situ*. 1, Heart. 2, Bronchiectatic abscess. 3, Track of operation wound.

of the neck. There was no evidence post mortem of sufficient disease in the upper air passages to produce these symptoms. Dr. Lees has suggested to me that there might have been an injury to the vagus or its branches at the time of the accident. This, along with a traumatic inflammation of the larynx and trachea, seems the most probable explanation. The lesion of the vagus or its branches would explain the profuse exudation of mucus into the larynx and trachea, where, even after laryngotomy, it accumulated to such an extent as to threaten the patient's life, and necessitated on more than one occasion the use of artificial respiration. The audible breathing, which came on about a fortnight after the accident, was evidently due to tracheal obstruction, being of the type most commonly heard in connexion with aneurysm of the aorta. It persisted after laryngotomy was performed, and was probably caused by the accumulation of viscid mucus in the trachea. Another point of interest is that for

Digitized by Google

three months the O'Dwyer's tube lay in the air passages without causing any symptoms by which its presence could be recognised. When he was sent out of hospital, the entire absence of any sign of it, after a most careful examination of the chest, led the authorities to believe that it had been coughed up and swallowed; and when he came to me a month later the chest condition was the same, and it was only from the purulent expectoration, the cough, and the loud breathing that I concluded that the tube was still there. Where was the tube at this time? I believe it was in the trachea. In support of this view there are the following facts:—(1) The audible breathing, the source of which could be localised by auscultation in the trachea; (2) the entire absence of signs pointing to its presence in a bronchus; (3) the sudden cessation of the loud breathing, which never recurred, after a severe fit of coughing; and (4) the onset immediately after of signs pointing to a block in the bronchus and collapse of the lung. On the other hand, it must be stated that in hospital the trachea was explored through the laryngotomy wound both by the finger and a probe, and that inversion was employed, with, in all cases, a negative result. As regards the operation, Mr. Lack proposed the resection of several ribs so as to allow of a thorough examination of the lungs, but I considered that the weakness of the patient was such as to render this unadvisable. Had the tube been reached through the operation wound, it would have been impossible to remove it by the same route without great danger of rupturing the important adjacent vessels. I have to express my great indebtedness to Dr. Leonard Guthrie and Mr. H. L. Lack for their generous and valuable assistance, and to Dr. H. G. Adamson for the drawing of the above engraving.

Carlton Hill, N.W.

EXPERIMENTAL RESEARCH ON TINNED PEAS, GREENED WITH SULPHATE OF COPPER, AND THE PHYSIOLOGICAL ACTION OF THIS SALT ON ANIMALS.

BY M. CHARTERIS, M.D.,
PROFESSOR OF THERAPEUTICS AND MATERIA MEDICA, UNIVERSITY OF GLASGOW;
AND
WM. SNODGRASS, M.B., C.M.,
MUIRHEAD DEMONSTRATOR OF PHYSIOLOGY, UNIVERSITY OF GLASGOW.

WE received for the purpose of this research four tins of peas from the sanitary authorities of Glasgow on Dec. 1st last, and on the same day commenced our examination of these on the following lines: 1. To determine that copper existed in the samples of peas we had obtained. 2. To find out their digestibility when placed in solutions similar to those of (*a*) gastric and (*b*) pancreatic juices, and also the digestibility of albuminate of copper in the same solutions. 3. To ascertain the physiological action of sulphate of copper on animals. Under these headings we will now give details of our experiments.

1. A tablespoonful of peas was taken from a tin which had been kept for ten minutes in boiling water and placed in a glass mortar. They were then acidulated with a little hydrochloric acid and crushed to a pulpy consistence by a glass pestle. The mass was then transferred to a platinum crucible and a zinc rod inserted through it, so as to touch the bottom of the crucible. A distinct deposit of copper was observed on the crucible, when, after the expiration of four hours, it was emptied and washed.

2. A tablespoonful of peas from the same tin, after being masticated, was placed in a glass vessel containing 4 oz. of water. To this were added 0·7 per cent. of pepsin and 0·2 per cent. of dilute hydrochloric acid. A tablespoonful of peas from the same tin was also masticated, placed in a vessel containing the same quantity of water, and to this was added a solution of pancreatin and carbonate of sodium. Both vessels were put on a sand bath and a uniform temperature of 99° F. maintained. At the end of an hour in the case of the gastric solution, and after an hour and a half the pancreatic solution was tested for peptone by the biuret test. In both cases a distinct red colour was observed, thus showing that digestion had taken place. A control experiment, in which no digestion had taken place, similarly tested, showed only a violet colour. The filtered fluid from the gastric solution was tested for copper by the insertion of a steel knife. After three hours this was taken out, and a distinct deposit of copper was observed on both sides of the blade. Mr. Tatlock, analyst for the city of Glasgow, testifies "that when an ounce of coppered green peas in a solution of ten grains of a peptonising powder and ten ounces of water is digested, the copper is dissolved out to the extent of 0·52 grain per lb. of the peas, which is equal to 2·05 grains of crystallised sulphate of copper." Mr. Clarke's analysis indicates a similar result. Doubtless sulphate of copper, however administered by the mouth, forms in the stomach an albuminate of copper which is rendered soluble by the digestive process. Yet as some strong statements have been made denying the possibility of this occurring, we now resolved to try the digestibility of an artificial albuminate of copper made (*a*) from white of egg and a weak solution of sulphate of copper, (*b*) made from curdled milk and a weak solution of sulphate of copper. These albuminates were dried, and a piece of each about the size of a lentil was placed in (*a*) solutions of pepsin and hydrochloric acid, (*β*) solutions of pancreatin and carbonate of sodium. The solutions were placed on a sand bath, and a temperature of 99° F. maintained.

Egg albuminate of copper.—Evidence of digestion commenced almost immediately in the acid solution, the blue colour first gradually disappearing, and at the end of one hour and ten minutes the digestion was complete. In the alkaline solution the disappearance of the blue colour was also observed, but the digestion was longer—viz., two hours.

Casein albuminate of copper.—With this albuminate the rapidity of the process was reversed, for it was completed in an hour in the alkaline solution, and at the expiration of two hours in the acid solution. Neither of these albuminates dissolved in strong acids, and this obvious fact has been by some observers brought forward as a test of their insolubility.

3. *Physiological action of sulphate of copper on animals.*—On Dec. 8th a full-grown rabbit was put into a basket, and a piece of bread spread with a paste of albuminate of copper was placed beside it. No other food was given. On the 9th the animal had eaten the greater part of the bread, and we calculated had taken seven grains of sulphate of copper. It was sickly, refused food, and dragged its hind extremities when it attempted to cross the room. The same day it was killed, the liver and kidneys taken out, cut up into small pieces, and two ounces of water and one drachm of sulphuric acid were added to the comminuted organs. Heat was applied for half an hour, and the fluid was filtered. A portion of this fluid was placed in a platinum crucible, and heat was used until the organic matter was burnt off. Strong nitric acid was added to the residue until it became of a pasty consistence, and a distinct deposit of copper was observed on the top of a steel knife which was placed in it. On Dec. 11th a full-grown rabbit was fed with greens over which a solution of sulphate of copper, seven grains to the ounce of water, was sprinkled, the greens being subsequently dried. By the next day the animal had taken the greater part of the greens. It was sickly and refused food, and did not move about easily. On the same day it was killed, and the organs similarly treated as in the former experiment. A copper deposit was also observed on a steel knife placed on the paste after the organic matter had been burnt off, and the residue treated with nitric acid. Into a portion of the filtrate kept for this purpose a needle was inserted, and at the expiration of twenty-four hours a deposit of copper was observed. The needle was again inserted and withdrawn after forty-eight hours, when it was found to be completely covered with copper.

We were, so far, satisfied with the results which accrued from its administration when given to rabbits, as these evidenced its absorption into the system; but as these animals are rather dainty in regard to their food, we resolved to try its action on a pig, which, as everyone knows, will swallow almost anything placed before it. As our time was somewhat limited, we gave sixty grains of the sulphate of copper in milk and meal to a young pig weighing nine pounds; but, contrary to our expectations, the animal refused this food for twenty-four hours. Therefore on Dec. 12th we made a weaker solution (ten grains to the ounce of water), and when this quantity was added to the milk and meal it was taken easily. The same quantity, ten grains, was taken for four days, and then the animal was killed. The liver and kidneys were boiled with water and

Digitized by Google

strong sulphuric acid, and a knife was placed in the filtrate. At the end of eighteen hours the knife showed, to the extent of its immersion, two inches, a complete covering of copper on both sides. The evidence of experiments 1, 2, and 3 was shown in court and their significance explained to Sheriff Birnie, who tried the case at the instance of the sanitary authority of Glasgow. The evidence for the prosecution and the defence is fully and correctly given in the *Chemist and Druggist*, in its issues of Jan. 1st and Jan. 15th. A careful reading of each shows that the evidence for the defence in no way traversed what we had done, and which was supplemented by such well-known chemists as Messrs. Tatlock and Clarke. Yet, in deciding for the defence, the Sheriff stated that "no new evidence had been brought forward." By his decision he sanctioned the use of a strong irritant metallic poison in food intended for consumption by human beings, the amount of which is not fixed, but is left to the discretion of foreign manufacturers over whom the authorities of our country have no control.

Glasgow.

ON

TWO CASES OF ANTHRAX SUCCESSFULLY TREATED BY EXCISING THE PUSTULE.[1]

BY T. PAGAN LOWE, M.R.C.S.,
HONORARY MEDICAL OFFICER TO THE EASTERN DISPENSARY, BATH.

THESE two cases occurred in March of last year. This is the first time, so far as I am aware, that the disease has been known in Bath.

A man named W——, aged thirty-eight, was first attacked, his wife contracting the disease fourteen days later. I saw him for the first time on March 11th, the seventh day of the disease. I found him suffering from a large malignant pustule on the right side of the neck, about the middle of the posterior triangle. The pustule consisted of a central dark-brown eschar, surrounded by a zone of flattened vesicles, outside of which was an inflammatory zone, the whole of the right side of the neck being enormously swollen and œdematous. The treatment I adopted was that of removing the pustule by an elliptical incision; and this included the whole area of vesiculation, together with a considerable portion of healthy skin on each side and the deep tissues beneath, so as to ensure complete eradication. The wound was freely irrigated with hot perchloride solution, and well dusted with iodoform before its margins were brought together by sutures. The patient made a satisfactory and uninterrupted recovery. Mr. Arthur Barker kindly examined the specimen and confirmed the diagnosis.

Mrs. W——, the wife, aged forty, who was assiduous in her attentions upon her husband, and to whom were entrusted the evening dressings, was attacked by the same disease fourteen days later. In her case the pustule appeared on the cheek. In the absence of proper home nursing I was obliged to send the case into hospital, where the pustule was excised by Mr. Stockwell, and its base freely cauterised. The operation in this case was performed on the fourth day, and was followed by rapid convalescence. In both instances the disease was inoculated by the finger nail, the husband having scratched his neck after washing some buffalo hide, and his wife her cheek after dressing her husband's wound. Both cases suggest that anthrax, when it attacks the skin, may remain local for a considerable time, and produce a mild affection as compared with the same disease when attacking internal organs. The bacilli of anthrax are known to have a marked preference for the superficial layers of the dermis, slowly penetrating into the deeper parts. Nevertheless, it seems very extraordinary that, in the case of anthrax, the excision of the focus of inoculation should arrest the progress of the disease. It may be explained on the hypothesis that the behaviour of the tissues towards the bacillus is very different from that towards most other infective micro-organisms, and an illustration is obtained of one form of tissue resistance. Very valuable information may yet be gleaned from observing more closely the strange sequence of events. One fact may be claimed as having been well established—i.e., that theoretical considerations should never deter anyone from operating, not only during the early stages, but at whatever period of the disease the cases present themselves. In fact, we have on record an ample number of instances in which complete success has followed excision during the later stages. It seems, moreover, that we have in the pustule a manufactory which supplies bacilli in unlimited quantities, and that, when this manufactory is removed, the microphages are well able to cope successfully with any organisms which may have escaped into the blood stream. The bacilli anthracis, although offering powerful resistance to cold and to strong solutions of carbolic acid, are quickly destroyed by low degrees of heat, a temperature of 120° F. being amply sufficient for the purpose. The disease in many localities is sufficiently common and dangerous to warrant legislative interference to prevent the importation of hides, except on the condition that, prior to distribution, they undergo a process of heating at, say, 120° F., for a given length of time. This process, whilst it would effectually stamp out the disease, would in no respect prejudice the commercial interest involved.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

RUPTURE OF THE DUODENUM.

BY R. HEELIS, M.D. DURH., L.R.C.P.L.

RUPTURE of the duodenum is said by Mr. Morris in Treves's Surgery to be of rare occurrence. Out of sixty-four recorded cases of ruptured gut only four were in that situation. Erichsen, on the other hand, considers it the most common position for a rupture, and accounts for this, first, by the fixity of that part of the gut and its consequent inability to escape pressure against the spine; and, secondly, by the fact of its not being protected by the costal cartilages. Bryant says rupture of the duodenum is very rare, but that it is most common at the upper end of the jejunum, on account of its fixture to the duodenum. In view of this diversity of opinion, a report of a case of rupture of the duodenum which I have recently examined may be interesting.

On July 23rd, about 3.30 P.M., a boy aged sixteen years, employed at a neighbouring colliery, whilst playing about on the bank was caught between a post and a tub drawn by a horse, the side of the tub hitting him in the right loin and forcing his abdomen against the post. In his belt he wore a bull's-eye lantern which caught against the post and was doubled up by the force of the collision, and driven against his abdomen and right groin. He fell down screaming with pain, and after having been given some brandy-and-water was driven home. I did not see him until three or four hours after the accident, when I found him lying in bed on his left side with his legs drawn up, groaning. He was not collapsed, and had a steady pulse; the abdomen was rigid and concave; there was a slight swelling in the right groin; no bruise in the loin or over the abdomen. He had vomited once before I saw him, there was no blood in the vomit; he had also passed urine, which did not contain blood. The principal tenderness was just above the right groin. He was given full doses of opium, under which the pain disappeared to a great extent.—July 24th: Had passed a fairly good night, but had vomited once or twice. On my visit I was surprised to find him downstairs, and still more so to hear that he had walked down. His pulse was good; his abdomen not distended; chief tenderness above the right groin as yesterday. Vomited bilious matter during the day, but ceased vomiting after he had had some ice. During the following night he died comatose, thirty-seven hours after the receipt of the injury.

Necropsy, thirty hours after death.—Advanced decomposition. The abdomen was greatly distended; there were gas in the abdominal cavity and some extravasation of blood between the muscles in the right loin. The peritoneal cavity contained a small quantity of bloody serous fluid and the intestines were not adherent or lymph-coated. The small intestines below the duodenum were removed in order to

Digitized by Google

get a view of the seat of injury. The colon, where it was in relation with the duodenum, was constricted for three or four inches and slightly bruised. Between it and the duodenum there was an oozing of bile-stained fluid through several small holes in the peritoneum, and on removing that membrane from the front of the bowel a large rent was revealed at the junction of the second and third portions on the right side of the second lumbar vertebra, involving fully two-thirds of its circumference. The edges of the rent were ragged and the bowel was bruised for about two inches above it.

The noteworthy points about the case seem to be the slight amount of shock in proportion to the gravity of the injury, and the delay in the setting up of severe general peritonitis. They are both explained by the fact of the rent being retro-peritoneal, the small holes in the peritoneum admitting only of a small and gradual extravasation of bowel contents. The absence of severe shock may have been also due to the escape from pressure of the great sympathetic ganglia. If the patient had been kept entirely at rest and supplied sooner with ice, I believe he might have survived the injury a good while longer, though the case was beyond the help of even present-day abdominal surgery.

Nottingham.

THE ADMINISTRATION OF CHLOROFORM.

BY ARTHUR COURT, M.B. CAMB.

IN view of the recent lamentable number of deaths from chloroform reported in the medical journals, I wish to bring forward this case of primary heart failure occurring during its administration, thinking it may possibly be of interest to the readers of THE LANCET.

The patient, H. B——, aged thirty, was the wife of a farmer. She had previously enjoyed good health. She had borne four children and was at the time of operation four months pregnant. On Nov. 6th, 1891, she pricked the index finger of her left hand with a rusty pin. This was followed by destructive inflammation of the tendon and metacarpo-phalangeal joint, the inflammation afterwards spreading into the palm of the hand; she had a sharp attack of septicæmia, and it was considered necessary to amputate the useless finger. The temperature having been normal for a week, on Dec. 22nd, at 10 A.M., I attended to give chloroform. She had had no solid food since the previous day, but was allowed some egg and brandy before my arrival. The heart was normal, with the exception of the sounds at the apex, which were remarkably sharp and clear. Pulse 80, small and easily compressible. The patient being placed in the supine position, I proceeded to administer chloroform on a Skinner's inhaler, commencing with half a drachm of chloroform, and after that a drachm of a mixture of equal parts of chloroform and ether. The breathing was regular and deep, and she came under the full influence of the anæsthetic in about three minutes. My father, who was operating, quickly amputated the finger. At the same time she suddenly became blanched, the pupils widely dilated, and the pulse ceased to be felt either at the temples or wrist. The breathing was, however, maintained. My father at the same instant saw that all was not right, for nothing but a little venous oozing escaped from the stump. I immediately hung her head over the edge of the table and pulled out the tongue, and then the breathing ceased. Fortunately I had at hand a hypodermic syringe filled with ether, which was quickly injected. We then took her by the waist and suspended her head downwards, and the colour gradually returned to her face, and the breathing became short and gasping. We replaced her on the table; but she at once relapsed into her former state, and the suspension had to be repeated. Again she rallied, and at last we succeeded in getting her round. The pulse remained very feeble, and she had several severe syncopal attacks during the day. She eventually got quite well.

I have no doubt that in this case the heart was primarily at fault, enfeebled by an attack of septicæmia in a pregnant woman, and that ether should have been the anæsthetic chosen in place of chloroform. I certainly believe that the suspension of the patient was the means of bringing about a satisfactory result.

Staveley, Chesterfield.

A CASE OF DOUBLE INTERNAL STRANGULATION BY THREE ADVENTITIOUS BANDS; ABDOMINAL SECTION; DEATH.

BY R. MUZIO WILLIAMS, M.D. LOND.,
AND
JOHN R. LUNN, F.R.C.S. EDIN.

THE curious condition found at the necropsy of the above case makes us venture to offer a brief *résumé* of it, especially as it illustrates to a remarkable degree the extreme difficulties to be contended against in the correct treatment of these formidable cases—difficulties principally arising from the impossibility of diagnosing correctly the exact anatomical lesions which have caused the strangulation, for they differ in almost every individual so affected.

T. B——, aged fifteen, came under our care on May 9th, 1891, with the following history:—He had always enjoyed good health until a fortnight ago, when he was attacked with severe diarrhœa, great abdominal pain, and frequent vomiting. He said that the attack commenced very soon after he had carried thirty-two rolls of paper (42 lb. weight) a distance of four miles. On first being seen the patient proved to be a well-nourished boy. The face showed great signs of suffering. Pulse small and rapid; temperature subnormal; pupils dilated; legs drawn up; abdomen much distended and tympanitic on percussion; some feeling of resistance in the right iliac fossa (the bowels had not been opened for two days); vomiting after all food. By May 12th the patient had become much worse in spite of treatment. Bowels still obstructed; vomited matters now dark brown. A distinct swelling could be felt in the right iliac region, which moved somewhat on change of position. It was decided that the patient's only chance of life was to make an abdominal exploration. On the abdomen being opened by a four-inch incision, and the much-distended gut being pushed to one side and covered by hot sponges, a broad inflammatory band was noticed passing to the right iliac fossa, all the parts in that region being much matted together; the band was an inch and a half broad and quarter of an inch thick, and was constricting the small gut beneath. On endeavouring with great difficulty to get it free some adhesions gave way, disclosing a collection of pus deep seated amongst the intestines and shut off by by adhesions. Into this pus-containing cavity the gut had sloughed and was very black. The patient having become very collapsed, the ragged opening was hastily made into an artificial anus by being stitched to the abdominal wound. The peritoneum was washed out and the wound dressed in the usual antiseptic way. The patient died the following night. At the necropsy the band noticed during the operation was found to arise from the mesocolon; it was seven inches long and constricted the small gut at a point eight feet from the stomach. About two feet below this was a second band, arising from a portion of the small intestine and passing to the right iliac fossa. It constricted the bowel by causing a sharp bend, and thus helped to form the first strangulated loop, part of which was protruding into the abscess cavity, and was gangrenous. There was a second strangulated loop about a foot in length, situated six feet from the stomach—dark, congested, and slightly gangrenous, with a small sloughing ulcer on its internal surface. It had become pushed beneath a third band, four inches long, passing from the great omentum to the cæcum.

St. Mark's-road, North Kensington, W.

A CASE OF ANÆMIA, CONSEQUENT UPON LUNG DISEASE AND STARVATION, TREATED BY TRANSFUSION OF BLOOD AND SALINE FLUID.

BY JOHN R. PHILPOTS, L.R.C.P. & S. EDIN.

MRS. H——, aged sixty-six, but looking older, first came under my care on Aug. 31st, in a weak and emaciated condition, weighing about 7½ st., and with a history of antecedent lung mischief and hæmoptysis. Her appetite was bad, and became worse, although a variety of different

Digitized by Google

foods were presented to her. At the commencement of October, 1891, she took only about one pint of milk, one egg, half a plateful of soup, half a wing of chicken, or an equivalent quantity of meat, about a tablespoonful of pudding, three cups of tea, a slice of bread-and-butter, and a teaspoonful of brandy. These quantities were diminished by Oct. 8th, when the pulse was flickering and 98 per minute, the patient refusing to take food. Transfusion of blood and saline fluid was then performed by Dr. C. E. Jennings, assisted by Dr. Masters and myself, the blood being furnished by a son of the patient, a robust man aged thirty-five. The operation was performed after the method described in Dr. Jennings's book,[1] the skin over the veins of the arms of the giver and receiver being cocainised. Twenty-six ounces of saline fluid were used, the major portion being infused into the giver's veins as a substitute for the blood transfused into the receiver. The wounded veins were ligatured with catgut, and the incisions have healed by first intention. As the result of this operation, the giver's face became perceptibly paler in colour, whilst the pallor disappeared from the face of the receiver. Scarcely any pain was felt during the operation by either person, and the giver was talking as though nothing were happening whilst the saline fluid was replacing his blood. After the operation the receiver's pulse fell to 80, and became full and strong, the improvement being maintained. Temperature normal. She is better in every respect, and takes as much food as is offered her now—viz, half a pint of new milk at 7.45 A.M.; a breakfast-cupful of bread-and-milk at 9.30 A.M.; a teacupful of bovril at 11.30 A.M.; a glass of milk with an egg beaten in it, and milk pudding, at 1.30 P.M.; a breakfast-cupful of Benger's food at 4 P.M.; a breakfast-cupful of bovril and milk at 6 P.M.; bread-and-milk at 8.30 P.M.; beef-tea and toast at 10.30 P.M. On Oct. 15th a whiting, instead of milk-pudding, at 1.30 P.M. During the night the patient took a quarter of a pint of egg-and-milk and a tea-cupful of bovril. She walks well and sleeps fairly. Since Oct. 8th five sleeping-draughts have been administered. There are crepitations over the front of the left lung, and tubular breathing posteriorly.

Parkstone.

ORCHITIS FOLLOWING INFLUENZA.

By J. E. BRISCOE, M.R.C.S.

THE following case is of interest in connexion with that of acute orchitis following influenza, reported by Mr. Harris.[2]

On Dec. 20th, 1891, I was called to a patient, W. W——, aged thirty-two, out-door labourer. He had been ailing for five days, worse the last two, but had continued working up to the afternoon of the previous day. He complained of pain in the joints and back, and had a white coated tongue. Temperature 101·6° F. He had had no headache; and a chronic cough, which had been worse some days before, was now much better. Bowels open; lungs and heart normal. He mentioned that two days previously he noticed pain in the right testicle, and the day before (Dec. 19th) found it swollen. On examination I found it enlarged and tender, but neither so large nor so tender as is often observed in cases of acute orchitis, there being no effusion into the sac, and no epididymitis. In the absence of symptoms or likelihood of gonorrhœa, of history of injury, and of parotitis, I was at a loss to explain the orchitis, except as an unusual but possible concomitant of rheumatism. The patient was ordered to support the scrotum, to take light diet, and given salicylate of sodium in ten-grain doses every four hours.—Dec. 22nd: Patient up; pain in back gone; temperature normal; testicle improving, but still slightly painful on pressure. I omitted the salicylate and gave a mixture of tincture of nux vomica, compound spirit of ammonia, and chloroform water.—27th: Convalescent but weak; all swelling and pain in testicle gone.—Jan. 4th, 1892: Returned to work.

This was, after all, probably a case of influenza, and the orchitis similar to that described by Mr. Harris. The absence of headache throughout (in which he persists) is unusual.

METROPOLITAN HOSPITAL.

A CASE OF PORTAL PYÆMIA; NECROPSY.

(Under the care of Dr. HOWARD TOOTH.)

THE following case is an illustration of pyæmic infection, the source of which was only discovered at the post-mortem examination, and presented no clue during life. The disease was evidently caused by the suppurating mesenteric glands, and the limitation of the secondary abscesses to the portal system is noteworthy. It is remarkable that no ulceration or other cause for infection was found in the intestines. The case was at first supposed to be one of enteric fever, but the temperature was more irregular and remittent than is usually found in this disease, even in children. The frequent rigors were also against this view. For the notes of the case we are indebted to the house physician, Dr. C. F. Marshall.

Ernest B——, aged six years, was admitted to the Metropolitan Hospital on Oct. 20th, 1891, with a history of ten days' headache, abdominal pain, and rigors. The rigors had occurred several times a day, and were followed by profuse sweating. The bowels had been confined until three or four days before admission, when diarrhœa began.

On admission, the child was pale, and rather wasted. The tongue was red and beefy, with a central glazed strip on the dorsum. Pulse 120, regular, rather small, and dicrotic. Temperature 103·4°. In the lungs were some subcrepitant râles, but no other signs. The abdomen was somewhat distended; the spleen was felt about an inch below the ribs. There were no spots. No albuminuria. There was a soft systolic murmur, apparently functional in character.

The progress of the case was as follows:—

Oct. 25th.—Condition much the same; no further signs or symptoms. Several rigors since admission. Temperature 105°. Diarrhœa. Pulse 104.

30th.—Diarrhœa improved; tongue cleaning. Temperature 101°; pulse 120.

Nov. 4th.—Tympanites. Has lost flesh since admission. Slight jaundice. Temperature 101°; pulse 140.

5th.—Jaundice increased. Tympanites not so great. Liver enlarged and very tender. Spleen unaltered. General condition worse. About 11 P.M. the child rapidly got worse, and died about 1.30 A.M. on the 6th. During the day the breath had a distinct pyæmic odour.

The temperature chart was very irregular, and with frequent remissions. Rigors were frequent during the first week, after this not so frequent.

Necropsy.—The liver was uniformly enlarged and completely riddled with pyæmic abscesses, some of which were nearly bursting on the surface. The branches of the portal vein were full of pus. The mesentery was thickened and all the mesenteric glands much enlarged, resembling the condition in tabes mesenterica, but none of the glands were tubercular. Several glands near the cæcum were suppurating, and one gland near the duodenum was in the same condition. The whole of the alimentary canal was carefully examined for ulceration, but no trace of this was found at any part. There was no sign of typhlitis or perityphlitis, and the Peyer's patches were normal. The spleen was much enlarged; all other organs normal. No abscesses were found in any other part.

LONDON COUNTY ASYLUM, HANWELL.

A FATAL CASE OF ABSCESS OF THE LIVER CAUSED BY THE PRESENCE OF A NEEDLE.

(Under the care of Mr. J. PEEKE RICHARDS, Medical Superintendent of the Female Department.)

THE cause for the formation of the suppuration in the liver in this patient must certainly be put down amongst the rarest of those met with in practice. Lunatics appear to

Digitized by Google

recover at times from injuries of considerable severity with greater ease than people who are not affected mentally. It is often impossible to prevent the self-infliction of minor injuries such as that described, or to find evidence of them afterwards, and usually they can be inflicted with impunity. This case is evidence of the serious consequences which may ensue, and, curiously, Mr. Richards recorded in our columns last year[1] the account of a case in which the patient died from pericarditis and hæmorrhage into the pericardium, the result of the lodgment of a needle, the presence of which was unsuspected until the necropsy revealed it.

T. G——, aged fifty-two, a widow, was admitted into the asylum on May 4th, 1888, having been transferred here from another asylum, where she had been for a little over a year. She was labouring under chronic melancholia, and had distressing delusions, fancying that someone was going to tear her to pieces. She had hallucinations of hearing, at times keeping up long conversations with imaginary persons. She was very industrious, employing herself at needlework nearly all day long; in fact, if she had no work to do she became very unsettled and used bad language. Nothing unusual was noticed about her until the morning of Oct. 9th, 1891, when she complained of pain under the left clavicle and in the left supra-scapular region. These parts were examined, but nothing wrong was detected. In the afternoon of the same day she told the charge nurse of her ward that on the previous night when she went to bed she had run a needle into her chest, and when asked why she had done so, replied that "she had felt all day whilst at needlework that every stitch she made she ought to have run the needle into herself instead of the work." The circumstance was at once reported to Mr. Richards, and both he and Mr. Holderness examined her, but no trace of a needle could be found, nor was there any mark or spot which would indicate that anything had been inserted into the part where the patient said she had pushed in the needle. She complained of pain on pressure over the fifth left intercostal space, just below the heart. She was ordered to bed in the infirmary, and placed under constant supervision day and night.

On Oct 10th her temperature began to rise, but it did not exceed 100° for six days. On the 17th the thermometer recorded 102°, and it mounted gradually higher and higher until the 20th, when it reached 104°. She complained from the time of her admission to the infirmary of her inability to swallow solid food, as it caused her much pain. On October 20th fluctuation was perceptible over the spot where she always said there was pain on pressure. An abscess gradually formed there, and on the 22nd it was opened, when about four ounces of thick blood-stained pus were let out. The opportunity was then taken of thoroughly exploring the abscess cavity, but no trace of a needle could be found. She appeared to improve for a few days, the temperature dropping slightly, but on the 26th it was noticed that the area of cardiac dulness had increased, and that there was marked dulness over the lower part of the left chest, and increased vocal fremitus over the upper portion. About this time a change was noticed in her mental condition: she developed the delusion that she had murdered her husband, and she became very restless and excited. The abscess continued to discharge pus, and she gradually sank, and died on Oct. 28th, twenty days from the time she said she had inserted the needle.

At the post mortem examination a needle an inch and three-quarters in length was found embedded in the left lobe of the liver, the blunt end being on a level with the upper surface of the organ. The whole liver was very much enlarged, weighing 87 oz., the left lobe alone weighing 29½ oz. The whole of this portion of the liver was occupied by innumerable abscesses, from the size of a pea to that of a walnut. They all seemed to be distinct and not to communicate with each other, and they contained thick creamy pus. The needle itself was surrounded by one of the larger collections of matter. There were no abscesses in the right lobe, and the left lobe was so enlarged that it extended quite across the abdomen, and came in contact with the ribs on the left side. There was a large abscess cavity over the left lower ribs in the mammary region, and in the fifth intercostal space was a minute aperture communicating with an abscess the size of an orange, situated between the under surface of the ribs and the upper surface of the left lobe of the liver, and communicating through the diaphragm with the abscesses in the liver. The upper part of the left pleura contained a large quantity of clear fluid, which had considerably compressed the lung. The lower portion of the pleural cavity had become obliterated by the adhesion of its costal and parietal pleuræ. The pericardium contained about three ounces of clear fluid.

Remarks by Mr. RICHARDS.—In this case all through I was extremely doubtful as to whether the needle had really been inserted at all, as there was only the patient's word for it; but I thought that perhaps, as frequently occurs in the insane, the woman had experienced some amount of pain in the formation of the abscess in the submammary region, and from this uneasiness she had originated the delusion about running in the needle. I am very doubtful as to whether the act was committed with any suicidal intent; but I am inclined to think that she was prompted to do so by one of those sudden impulses so extremely common in those of unsound mind, and in her case particularly so, as she had well-marked hallucinations of hearing, and may be a "voice" had instigated her to commit the act which caused her death.

[1] THE LANCET, vol. i., p. 1151.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

SUPRA-PUBIC DISLOCATION OF HEAD OF FEMUR; FAILURE OF ATTEMPTS AT REDUCTION; LATER EXCISION OF HEAD OF FEMUR.

(Under the care of Mr. R. H. HUGHES.)

THE account of this case describes a displacement of the femur which differs so remarkably from the ordinary pubic one as to almost require a separate term to describe it. Instead of the head of the bone lying in one of the usual situations, (*a*) on the pubic bone, or (*b*) beneath the anterior inferior spine of the ilium, it was forced by the blow high up into the abdominal wall, to such an extent that, although the patient was only eleven years old, the amount of shortening exceeded that usually found in the adult by an inch and a half. Such an amount of displacement, permitting as it did both trochanters to be felt from the front, implied a considerable laceration of the soft parts attached to the upper end of the femur, and indicated to some extent the severity of the injury which caused the dislocation. Excision of the head of the femur has not been performed for irreducible dislocation of that bone in many recorded instances. Kirn[1] found only twelve such. Of these, nine recovered and three died. The majority of the operations have been performed on patients the subject of dorsal dislocation, and nothing short of removal of the head of the bone permitted reduction to be effected. For the notes of this case we are indebted to Mr. W. Gifford Nash, late house surgeon.

T. B——, a boy aged eleven, was admitted on Sept. 20th, 1890. He stated that he was running behind and pushing a swinging boat that afternoon when he slipped under it. On its return the boat struck his right knee, dislocating the hip. He was seen by Mr. Hughes, who, with Mr. Lucy's help, attempted reduction under chloroform. This failing, he was brought to the hospital for a further attempt with the pulleys.

On admission there was a contusion over the front of the right knee. The right leg was everted, abducted, and shortened to the extent of two inches and a half or three inches. The head of the bone could be seen and felt lying half-way between the umbilicus and Poupart's ligament. Both trochanters could easily be felt on rotating the limb. There was considerable blood effusion into the soft tissues around the joint. The femoral artery could be felt pulsating on the inner side of the small trochanter. Methylene was given, and reduction again attempted by means of pulleys and manipulation. The head of the bone could not be got below the pelvic brim by any means. He was then put to bed with a weight extension applied to the dislocated limb. In a few days there was widespread ecchymosis over the lower half of the abdomen, scrotum, perineum, and right thigh. Whilst awaiting absorption of the effusion he developed an attack of acute rheumatism, which delayed the operation until

[1] Beiträge für Klin. Chir., 1890.

Digitized by Google

Dec. 5th, when methylene was given, and an incision four inches long made over the neck of the femur. The head was exposed, and all the ligamentous and muscular attachments to the neck and great trochanter were divided. Traction was then applied without effect. The tip of the great trochanter was found to be separated, and a large amount of periosteum stripped off the back of the femur. At the back of the femur, connecting the shaft with the back of the acetabulum, was an elongated mass of bone, formed by the periosteum which was stripped from the back of the femur. The neck of the femur was sawn through and the head removed. Traction was again applied without result. The wound was then closed. Six weeks later, when he got up, there was two inches of shortening. In July he was seen, and was then able to walk well with a high boot. The hip was quite stiff, and about two inches of shortening present.

Remarks by W. G. NASH.—Not being able to find any record of a similar dislocation, I think this worth recording. The cause of irreducibility was never determined. The head of the femur could be brought down so that the neck rested on the ilio-pubic ridge, but the head itself could neither be dragged nor manipulated over it. The great force which produced the dislocation is shown by the large amount of periosteum stripped off the back of the femur. It was unfortunate that the resection of the head had to be delayed so long, as it gave time for so much new bone to be thrown out, but it would not have been safe to have operated early after the accident, when the tissues were so bruised and full of extravasated blood.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Madura Disease of Hand and Foot.—Ulcerative Endocarditis of Pulmonary Valve.—Toad attacked by Blow-fly Larvæ.—Thrombosis of Splenic Vein associated with Infarcts.

AN ordinary meeting of this Society was held on Jan. 19th, the President, Sir George Humphry, in the chair.

MR. A. A. KANTHACK exhibited a hand and foot affected with Fungoid Disease. They had both been amputated by Dr. Browning of Madura. There were two varieties of Madura disease: one, the yellow or pale variety, in which in the hollows formed by the disease there were found little yellow particles, looking like fish-roe; and the black, or melanoid kind, in which the hollows were filled with brownish-black masses. The two forms otherwise resembled each other closely in that there were numerous cavities in the soft tissues of the part, the bones likewise undergoing softening. The disease was undoubtedly due to a fungus, and the second, or black variety, seemed to be a degeneration of the first. If portions of the growth were placed in ether or chloroform, and afterwards well washed in caustic potash, small rounded bodies would be left which showed rays under the microscope, and which closely resembled actinomycosis. Outside the ray-like mass was an area of round cells, and this again was enclosed in a fibrous ring. Its reaction to staining was identical with actinomyces. In the black masses the central reticulated structure was present, but the rays or fringes had not been found.—Mr. D'ARCY POWER referred to a specimen of the yellow variety of Madura foot which was in St. Bartholomew's Hospital museum.—Dr. ROLLESTON said there was a foot of the black variety in St. George's Hospital museum, which he had examined, but was unable to make out satisfactorily the structure of the black bodies.—Dr. WHEATON asked if these fungi could be stained by Gram's method; if they could not be so stained they were not actinomyces. Last year he showed a fungus affecting the lung which could not be stained by Gram's method, and which was not actinomyces.—Mr. KANTHACK, in reply, said that the specimen stained easily with aniline dyes. It was quite impossible to stain actinomycosis bovis with Gram's method, unless the saponaceous and calcareous matter were removed. And when actinomyces had undergone degeneration it could not be stained by Gram's method, though this was easily effected by Ehrlich's hæmatoxylin. Black masses of actinomyces had been found in the œsophagus, but their colour was easily discharged by spirit.

Dr. ARNOLD CHAPLIN read a paper on a case of Ulcerative Endocarditis affecting the Pulmonary Valve, taken from a girl under the care of Dr. Sainsbury at the Victoria Park Hospital. The patient was a waitress aged eighteen; she was admitted to the hospital on Aug. 11th, complaining of great dyspnœa and palpitation. On admission she was found to be very anæmic, and the temperature was between 99° and 100° every evening. The pulse was 126, the respiration 30, and the urine natural. On auscultating the heart there was heard at the apex a blowing systolic murmur, conducted round some way into the axilla; and over the pulmonary artery there was a loud systolic bruit, followed by a short diastolic murmur, which was conducted across the sternum to the right. The right side of the heart seemed to be enlarged; the lungs were healthy. On Aug. 25th severe pyrexia set in, the temperature rising to 104° or 105° every night, and this hectic character of the temperature was persistent until the end of the case. On Sept. 1st the spleen was noticed to be enlarged; on the 23rd and several times afterwards the skin became spotted with a petechial rash, which disappeared after a few days. The murmur at the base altered from time to time, sometimes becoming more distinct than at others. On Oct. 14th the patient had hæmoptysis, half an ounce of blood being brought up, and crepitations now appeared at the bases of both lungs. The pulse and respiration increased in frequency, and the patient died on Nov. 11th. At the necropsy the pulmonary artery was found filled with a vegetation adherent to the wall of the artery and joined to a small vegetation upon the pulmonary valves. There was a small vegetation also on the mitral and aortic valves. The lungs showed puckered scars at the base and a recent infarct at the right base. There were no infarcts in the spleen or kidney.—Dr. TURNER said that three years ago a case came under his care in the Children's Hospital with a similar lesion. The child was eleven years of age, and had fallen ill two months before. She was short of breath on exertion, cyanosed, and there was pyrexia. Over the pulmonary artery there was a loud bruit, and a diagnosis was made of congenital malformation of the pulmonary valve, together with pulmonary tuberculosis. The temperature suggested either a septic condition or tuberculosis. While under observation she had attacks, during which she became livid, cold, and torpid for a time, then coming round, the pulse being very feeble. At the necropsy a condition was found very similar to that in the specimen shown, but more severe. There was a congenital stricture behind the valve and a communication between the ventricles. The attacks, he thought, were due to increase in the thrombotic mass. Dr. Peacock has likewise described a similar case.—Dr. HECTOR MACKENZIE two years ago showed a card specimen much like that shown, and there was also a communication between the ventricles. At St. Thomas's Hospital, out of thirty-eight cases of ulcerative endocarditis only two occurred on the right side. In both of these the left side was likewise affected to a less degree; both were in females, and one was associated with pelvic inflammation.—Dr. BRADFORD asked if there were any history of injury, bone disease, or other septic trouble. One or other of these conditions had often been found in association with right-sided disease.—Dr. CHAPLIN, in reply, said there was nothing to account for the disease; the only other lesion was an old lateral curve of the spine.

Dr. LEONARD GUTHRIE showed a Toad whose mouth and nostrils had been attacked by the larvæ of blowflies, causing the death of the animal. Mounted specimens of the larvæ were also shown, with drawings of their structure. The toad when found seemed in fairly healthy condition, but the tip of the nose was discoloured, the nostrils were slightly enlarged and ragged, and emitted a frothy discharge. Within them could be indistinctly seen a mass of moving larvæ. Within thirty hours of capture the nostrils formed one large cavity, separated only by a thin septum of skin anteriorly, both eyes were collapsed, and their empty tunics lay in the cavity of the mouth, whilst the whole of the soft palate had been devoured by the larvæ, leaving the bones picked bare. Between three and four dozen larvæ were removed after the death of the toad. It was well known that toads and frogs were subject to such ravages, but until the present time no attempt to identify the larvæ had been successful. Dr. T. S. Cobbold had referred to the subject in the *Veterinarian* for 1880, but had been unable to name the maggots. Prof. Brauer of Vienna had kindly examined the larvæ now exhibited, and had pronounced them to be of the genus

Digitized by Google

Calliphoræ. The species was indeterminate, but was probably Erythrocephala magna or Vomitoria. The structure of the larvæ was described, and their mode of feeding and progression. They were not true parasites (such as the Batrachomyia of McLeay), for they speedily destroyed the life of their host. Yet it was difficult to explain why the mouth and nostrils of batrachians were always the sole parts attacked. It was obviously impossible for the fly to lay its eggs directly in the toad's nostrils, and the probable explanation was that the eggs were laid in the toad's mouth whilst a pregnant fly was being swallowed. Evidence was given to show that the number of toads in certain years was largely reduced by means of the blow-fly's larva. Parallel instances in which human beings had been attacked by the larvæ of these and other flies were given. Amongst others, Messrs. Coquerel and St. Paix of Cayenne had recorded many cases of convicts whose nostrils and eyes had been almost entirely devoured by the larvæ of the golden fly (Lucilia hominivorax) with fatal results.—Dr. PENROSE had seen a gamekeeper with a swelling on the wrist. On incising it the larva of a blowfly escaped.—Dr. BEAVAN RAKE said that in tropical countries maggots in the nose were not at all uncommon, and they were seen also in the meatus of the ear, especially in lepers; but they were also occasionally found in people in higher stations of life. He related an instance in which an engineer, while on a visit to Venezuela, was stung by a fly; a swelling formed at the side of the chin, and later a large larva was expressed from it. Several cases had also been published from Central America. One so seldon saw flies about these patients that it was very difficult to trace the way in which they became affected.—Dr. GUTHRIE, in reply, said that there was a specimen in the museum of the College of Surgeons which had been taken from the leg of Dr. Livingstone. Cases in which human beings had been affected were not at all rare, the larva of nearly every known fly having been found.

Dr. ROLLESTON showed a specimen in which the Splenic Vein was occluded with firm adherent decolourised clot. The superior mesenteric vein contained a thrombus which had softened down in the centre so as to be canalised. The inferior mesenteric vein was occluded with ante-mortem clot. Adherent clot extended into but only partially occupied the lumen of the portal vein. There was softened clot in the internal and external iliac veins on the left side. The thrombosis of the superior mesenteric and iliac veins was the oldest. The spleen weighed thirty-six ounces, and had large pale firm anæmic areas in the periphery separated from the rest of the organ by a zone of congestion of the shape and general appearance of infarcts, and which microscopically showed coagulation necrosis. The splenic artery was normal. The points of pathological interest in the specimen were: (1) The association of complete thrombosis of the splenic vein with death of limited portions of the spleen, so as to produce the appearance of infarcts due to embolism of the splenic artery; (2) the fact that these infarcts were anæmic and not hæmorrhagic, as from venous stasis would naturally have been expected. From a man aged twenty-nine, who died in St. George's Hospital under Dr. Ewart. He was admitted with profuse hæmatemesis; while convalescent ascites and œdema of the left leg came on and death from asthenia. During life the blood was examined without finding any evidence of leucocythæmia.—Dr. TURNER thought that there must have been vessels other than the splenic vein, by which a certain amount of blood could get away from the spleen, and there was evidence also that some of the splenic arteries were blocked. He explained the occurrence of the lesions in the following manner: When the splenic vein became thrombosed, increased vascular pressure in the spleen resulted; this produced interference with the circulation through the whole organ, and consequent interference with nutrition. In certain weaker branches of the splenic artery which became injured by this process thrombosis took place, and thus the areas of anæmia would be produced.—Dr. NORMAN MOORE remarked that the patient had had hæmatemesis, and asked if it had been often repeated. He related the case of a woman who had been under observation for twenty years, having first been in University College Hospital, under Sir William Jenner, for a severe hæmatemesis. The spleen was at that time enlarged, though it diminished under observation. On three subsequent occasions she was admitted into St. Bartholomew's Hospital with copious hæmatemesis, and after the bleeding it was noticed that the spleen became reduced in size. Later she had such a severe hæmorrhage that she died in syncope. At the necropsy there was a partial clot in the splenic vein and a complete clot in the portal vein.—Dr. WHEATON said that a young man was recently admitted into St. Thomas's Hospital with an umbilical sinus. He had been in the tropics. The spleen was very large, and at the necropsy a large infarct in a state of suppuration was found in its lower end. There were also two smaller white infarcts in the organ. There was no disease of the arteries there or elsewhere.—Dr. ROLLESTON, in reply, said that he accepted Dr. Turner's explanation. The patient had suffered from hæmoptysis only once on admission; he had had none previously or afterwards. The cirrhosis of the liver present was very slight, and did not seem to account for the hæmatemesis.

The following card specimens were shown:—

Dr. F. C. TURNER: (1) Malformed Heart; (2) Partial Hydronephrosis of Right Kidney.

OBSTETRICAL SOCIETY OF LONDON.

The relation between Backward Displacements of the Uterus and Prolonged Hæmorrhage after Delivery and Abortion.—Dr. Apostoli's Method.

A MEETING of this Society was held on Wednesday, Jan. 6th, Dr. Watt Black, President, in the chair.

Dr. HERMAN read a paper on Backward Displacements, based on an analysis of 3641 consecutive out-patients at the London Hospital. The author showed by figures that backward displacements of the uterus are more common in multiparous women than in those who have not had children, that they are more common in those seeking advice soon after delivery or abortion than in those not applying for treatment until long after childbirth or abortion, that they are more frequent among those in whom delivery or abortion has been followed by prolonged hæmorrhage than in those in whom it has not, that prolonged hæmorrhage after delivery or abortion is more frequent in cases of backward displacement of the uterus than in cases without such displacements; therefore that there is a relation between backward displacement of the uterus and prolonged hæmorrhage after delivery and abortion. It was shown that these statements applied both to hæmorrhage after delivery and to hæmorrhage after abortion.

Dr. INGLIS PARSONS read a paper entitled "Twenty Cases of Fibroma and other Morbid Conditions of the Uterus treated by Apostoli's Method." Electrolysis, he stated, exerts two actions, a polar and interpolar. The former extracts acids and bases from the tissues near the poles, and produces a secondary caustic action; while the latter causes an exchange of atoms between molecules, some polarisation, and possibly slight osmosis. The electrical resistance of tumours varies greatly. It may be higher or lower than healthy tissue, and the results of treatment differ in consequence. Fibrous tissue and old hard tumours have a high resistance, while soft œdematous tumours are good conductors. The position and size of the tumour are important. If submucous it can be treated by the polar action, but if intra-mural by the interpolar only. A large tumour conducts better than a small one. The following points must be considered:—(1) The position of the tumour; (2) its relation to the abdominal wall; (3) its age and consistence; (4) its sectional area. Of fourteen cases of fibro-myomata hæmorrhage was stopped in all. The subsequent history, traced out for some years, showed no relapse in six cases, although in two of them the hæmorrhage threatened life. One patient always relapsed in a few months. Removal of the appendages was advised, but refused. In many cases the flow rather increased at first, but in one it was arrested by only six applications. Relief of pressure symptoms was obtained in most cases. One patient unable to walk recovered her power after a few applications; while another with bladder symptoms showed no improvement; the tumour was too hard to be affected by the current. Diminution in size only took place to a limited extent in most cases, but one tumour entirely disappeared, and pregnancy subsequently occurred, a result that could not possibly be obtained by removal of the appendages. Hysterectomy was afterwards performed on another patient, on account of the size of the tumour. Pain sometimes followed strong applications for a day or two, but soon went off,

Digitized by Google

while pressure pains were relieved. For galvano-puncture greater care was required on account of the risk of sepsis, and only an insulated trocar should be used so as to leave no sinus. The risk appeared to be very little, as no ill result ever followed in any of the cases. Unsuitable cases were—(1) Fibro-cystic tumours; (2) associated disease of the ovaries or tubes; (3) very old and hard tumours; (4) some which require no treatment of any kind. A case of hæmatocele showed no appreciable alteration after six applications. Two cases of dysmenorrhœa, due to anteflexion, remained unbenefited by the current. One case of neuralgic dysmenorrhœa was apparently cured. Menstruation was established in a girl of nineteen who suffered from primary amenorrhœa. The author concluded that Apostoli's treatment was of value in a large proportion of cases, because (1) it arrested growth, and might reduce the size, and even cause absorption, of an entire tumour; (2) it arrested hæmorrhage in most cases; (3) it relieved pain and pressure symptoms; (4) it did not prevent pregnancy.—Dr. PETER HORROCKS said there was no scientific evidence of interpolar action in the case of tumours. He said that clinically the negative pole was stronger than the positive; nasty ulcers might be produced if the negative wire touched the skin. He gathered from the context of the paper that by fibroma was meant fibro-myoma. He pointed out the difficulties of diagnosis, especially in small tumours, and he thought it was quite fair to doubt the accuracy of the author's diagnosis in Cases 1 and 8, and in the case in which he alleged that a tumour had entirely disappeared. Such disappearance, he thought, was greatly against its being a tumour in a pathological sense, and probably it was of an inflammatory nature. He pointed out that there was nothing mysterious about the action of electricity. It was a caustic, and any other caustic, especially heat, applied in the same manner and degree, would have equally good results; so that, whilst admitting that electricity was useful in some cases, he could not agree with the author's conclusions. What proof was there that electricity would arrest the growth of a fibro-myoma? He agreed that it would stop hæmorrhage and would not prevent subsequent pregnancy, but he was not equally sure that it would relieve pain and pressure symptoms in the majority of cases where these were present. But when this method was tried it was often so painful in itself that patients refused to continue it and would leave the hospital.—Dr. HERMAN agreed with most that Dr. Horrocks had said. He also could not agree to the diagnosis in the case in which a fibroid was said to have disappeared. The history seemed more like that of a hæmatocele from extra-uterine gestation, ending in natural recovery. The diversity of opinion in regard to the effects of electricity upon fibroids was in striking contrast to the unanimity about the results of removal of the appendages. He objected to the galvanising of the uterus in a girl nineteen because she had not menstruated.—Mr. DORAN offered remarks.—Dr. PLAYFAIR said some writers had undoubtedly exaggerated the claims of electricity, and probably this was the cause of the prejudice against it; but he pointed out that the opposition came chiefly from those who had given no time or trouble to mastering the undoubtedly difficult technique of its application. He had visited Apostoli, and had assiduously tried his method. Increasing knowledge and experience had not led him very materially to modify the conclusions he had already formulated elsewhere. He still believed electricity a substantial gain to gynæcology, though the process was complex, difficult and tedious, and not adapted for general use. That it possessed the power of promoting the absorption of fibro-myomata to a certain though limited extent he believed to be beyond question. He did not consider it to be an absolutely safe procedure. Electro-puncture was very different from electro-cauterisation. The number of cases in which mere diminution of size was of importance was very limited; hence he had practically abandoned this application of electricity, though he still thought it applicable in certain cases of fibroids impacted in the pelvis. He could not agree with Dr. Horrocks' attempt to minimise the value of Dr. Parsons' cases by questioning their diagnosis. He found the hæmostatic effect of the positive pole admirable in many cases, but not in all, and he thought this was due to the actual contact of the pole with the endometrium. Curetting and the application of caustics were quite inapplicable to most cases of hæmorrhagic fibroid where there existed a largely elongated endometrium. He quoted a case where caustics and the curette had been thoroughly applied, but always with temporary benefit. He tried electricity, and the lady, although only between thirty and forty years of age, had never menstruated since. He believed that theoretically electricity should be tried first in all bad cases of hæmorrhagic fibroid; but it was too costly and tedious in some cases, and then removal of uterine appendages should be performed. He was surprised Dr. Parsons had not mentioned the use of electricity in chronic uterine catarrh and other morbid conditions, such as membranous dysmenorrhœa.—Dr. ROUTH thought the entire disappearance of fibroids by electricity had been exaggerated. Soft ones disappeared more readily than hard ones. Electricity certainly did good and enabled persons to get about as if the fibroids did not exist. Applied to the cavity of the uterus the negative pole produced dilatation of the cavity and very often induced menstruation; the positive pole arrested hæmorrhage. He thought it scarcely kind to doubt the diagnosis of the cases brought forward by Dr. Parsons.—Mr. SKENE KEITH thought it hardly fair to cast doubts on the electrical treatment by suggesting that mistakes in diagnosis were sometimes made. He agreed very much with Dr. Parsons' conclusions, but thought in some cases surgical interference might be the better treatment.—Dr. INGLIS PARSONS, in his reply, said that he had in 1888 opposed the theory of interpolar electrolysis. In his experience the anode was more destructive than the cathode. The diagnosis in the majority of these cases was, from the size of the tumour, beyond a doubt. They had been seen by his colleagues. In one case he had stated in the paper that the diagnosis was an open question. He thought the tumour which disappeared was undoubtedly a soft fibro-myoma. She did not have amenorrhœa, but menorrhagia persisted for two years. He agreed with Dr. Herman regarding the treatment of primary amenorrhœa, but in this case the mother was very anxious for menstruation to begin. In fibro-myoma the menopause was often delayed five years or even more. He thought that acupuncture was much less dangerous when done with his own insulated trocar, because it did not leave a sinus as Apostoli's did. He had only lately used electricity for endometritis, but he had found that it would cure cases when all other means had failed.

The following specimens were shown:—

Dr. SHAW MACKENZIE: Sarcoma of both Ovaries.

Dr. HEYWOOD SMITH: An Abscess connected with the Left Ovary removed by Abdominal Section (Actinomycosis?).

Mr. BLAND SUTTON: (1) Dermoid Cyst showing Baldness of the Wall; (2) Dermoid Cyst associated with Fat in the Broad Ligament; (3) Hydrosalpinx.

Dr. BOXALL: Rupture of the Uterus.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

Mr. SHIRLEY F. MURPHY, President, in the chair.

Building By-laws.

AT a meeting held on Dec. 21st last a discussion was opened by Dr. LONGSTAFF, chairman of the Building Acts Committee of the London County Council, on Building By-laws in relation to the Air and Light around Buildings. The present law, he said, fixed the width of all new streets at not less than 49 ft., but in one 50 ft. wide the buildings on each side might be 90 ft. high. This height the committee would reduce to 75 ft., or not more than one and a half times the width of the street, though they were not prepared to raise the minimum street width, as had been done in the model by-laws of the Local Government Board, which fixed it at 66 ft. The space in the rear of every house they would increase from 100 to 150 square feet; but as hitherto this might be covered over by a building of one storey, the model by-laws required a space 25 ft. deep, free from all buildings and extending through the entire width of the premises; this was better, but no regard had ever been paid to the different height of buildings. The committee had, however, drafted an amendment which they hoped to have introduced into the Bill, presenting the advantage of adapting itself to the varying height of houses. It was that an open space 10 ft. deep, and free from any buildings be reserved along the entire width of the rear of the site, and that no part of the buildings, chimneys alone excepted, rise above a line drawn at an angle of 45° from the ground at the further boundary

Digitized by Google

of the space in the rear to the eaves or most prominent point of the main body of the building. This was the angle established by custom in the question of "ancient lights," which, however, applied only to old houses, but was found to work satisfactorily. In dealing with existing buildings which were not in accordance with the new regulations they were willing to respect rights of which the owner might be in actual enjoyment, permitting their re-erection to the same height as before; but they would not recognise the potential right to put up a building of 90 ft. high on the site of one of 20 ft. They did not, however, propose to deal with "wells" or courts enclosed within large blocks of houses. —Dr. ARMSTRONG said that in Newcastle all new streets must be at least 40 ft. wide, and have in their rear a "back street" or thoroughfare 20 ft. wide on which no houses might face.—Dr. L. PARKES deprecated the practice of building huge blocks of artisans' dwellings, or of mansions separated only by narrow, ill-ventilated spaces or courts, maintaining that the intervals should be equal in width to the full height of the houses. He thought that a clause might be introduced into the Bill requiring plans and elevations of all proposed new buildings to be submitted to the local authorities, and that if they considered them likely to be dangerous to health the County Council should refuse their sanction. At present nothing could be done until they were occupied.—Mr. WYNTER BLYTH held that, while the County Council might well make by-laws, the actual supervision could be efficiently carried out only by the local authorities. If all plans were submitted to the local medical officer of health, to be reported on by him to the local authority, the annoyance and expense consequent on the refusal of certificates under the Customs and Inland Revenue Act would be saved. —The PRESIDENT considered that the width of streets should be one and a half times the height of the houses, and that the application of the angle of 45° in the case of all rooms used for habitation would meet the difficulty of enclosed courts. The amount of light, apart from air, depended on the orientation or aspect of the house, and he gave Vogt's formula for determining the possible illumination under all circumstances:—

$$\frac{L}{H} = \theta \times (30^\circ + \delta)\cos a.$$

When H = height of house. L = width of street &c. θ = angle of solar light. δ = angle of direction of street with the meridian.

It was then unanimously resolved that the Society represent to the President of the Local Government Board the urgent need for the amendment of the London Building Act so as to secure an adequate supply of air and light around and within all buildings, and that the amendment proposed by the County Council be accepted and introduced into the Bill.

HARVEIAN SOCIETY OF LONDON.

THE President (Mr. H. Cripps Lawrence) delivered the annual presidential address, in the course of which he gave an account of the main objects of the Harveian Society, and spoke of the means by which these might be best accomplished. Dealing with the salient points of Harvey's scientific work, which suggested to the individual members of the Harveian Society how best to carry out the work of the Society, he said:—

"One of the most important of these in reference to scientific investigations is to be found in a letter from Harvey to John Riolan the younger, 'in opposition to those who repudiate the circulation because they cannot see the efficient or final cause of it, and who exclaim, *Cui bono?*' wherein he propounds these axioms: 'Our first duty is to inquire whether the thing be or not, before asking wherefore it is.' Again, 'He who truly desires to be informed of the question in hand, and whether the facts alleged be sensible, visible, or not, must be held bound either to look for himself or to take on trust the conclusions to which they have come who have looked;' and assuming the witnesses to be credible, he adds, 'there is no higher method of attaining to assurance and certainty.'[1] Next to scientific *caution*, Harvey exhibited *toleration*. Aikin refers to this when he tells us that Harvey was 'cheerful, candid, and upright; he was not the prey of any mean or ungentle passion. He was as little disposed by nature to detract from the merits of others, or make an ostentatious display of his own.' Again, 'the many antagonists whom his renown and the novelty of his opinions excited were, in general, treated by him with modest, temperate language, very different from their own; and while he refuted their arguments he decorated them with all due praises.'[2] So, too, Dr. Ent,[3] in his preface to 'Harvey's Researches on Generation,' adds, 'and we have evidence of his singular candour in this, that he never hostilely attacks any previous writer, but ever courteously sets down and comments upon the opinions of each,' regarding it as 'argument of an indifferent cause, when it is contended for with violence and distemper, and that truth scarce wants an advocate.' Harvey's character, too, was *modest* and *generous*. Of the truth of this we have evidence in his solicitude for the welfare of the College of Physicians. Having built for the college 'a library and a repository for simples and rarities,' on Feb. 2nd, 1653, 'Harvey was present on the opening occasion, having provided a handsome entertainment and formally handed over the title-deeds and entire interest of the building in a speech of the utmost benevolence and good-will.'[4] On Sept. 30th, 1654, being elected President of the College in his absence, 'he declined on the next day, owing to his age and infirmities, recommending the continuance in office of Dr. Prujean, under whose prudent management and fostering care the affairs of the College had greatly prospered.'[5]

Once more, Harvey was not only the greatest scientist of his day, for he had 'the rare distinction of standing at the head of three departments of science in England—comparative anatomy, physiology, and medicine,'[6]—but he was a man of widely cultivated mind outside his professional work, fond of reading the classics; and still a learning mathematician in his old age. Harvey knew the men of letters and science of his day, as Dr. Dickinson, in his recent Harveian oration pointed out.[7] 'It is worth noting that Harvey's long life made him the contemporary of the four greatest men whom England has produced—Shakespeare, Bacon, Milton, and Newton,' and of others such as Hobbes, Dryden, Boyle, and Cowley. With all this culture he was an independent searcher after truth, and albeit vivisection became necessary thereto, he was reverent in the use of that means. Harvey, though by no means eager in the pursuit of wealth, set a good example to his professional brethren in making a will while in the possession of his faculties, and reading it over even within six months of his death, at eighty years of age. Active in religious sentiment, 'he evinces,' as Dr. Willis tells us, 'true and elevated piety throughout the whole course of his work on Generation, and seizes every opportunity of giving utterance to his sense of the immediate agency and omnipotence of the Deity.' So lived, so died, one of the great men whom God, in virtue of His eternal laws, bids to appear on earth from time to time, to enlighten and ennoble mankind.'

ROYAL ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Obstetrical Section was held on Nov. 27th, Dr. Atthill in the chair.

Cæsarean Section.—The PRESIDENT (Dr. Horne), having returned his warmest and best thanks to the Fellows of the Royal Academy of Medicine for having elected him as president of the Section of Obstetrics, read an address on this subject. His firm conviction was that there are many infants annually sacrificed who might be saved if the medical profession would recognise the fact that a majority of such cases could be saved by prompt surgical interference. He gave a short *résumé* of the history of the operation, and did not consider it required more than ordinary surgical skill for its performance. He laid special stress on the treatment of the uterine wound, as advocated by Sänger of Leipzig, and paid a

Digitized by Google

tribute of respect to Lister, as having restored the Cæsarean section from the limbo to which it was consigned to its proper place in the surgical art by means of antiseptics. On the early recognition of pelvic deformity depended the success of Cæsarean section.

Removal of a Pin from the Bladder.—Dr. LANE exhibited a pin about two inches in length which he had removed from the bladder of a young lady. The patient was seen on the day the pin escaped into the bladder, and was with ease felt by examination per vaginam. The head was resting against the posterior wall of the bladder and to the right of the uterus, the point being directed forwards and to the left side of the orifice of the urethra. Owing to certain reasons the attempt to remove the pin had to be postponed for three days, and when the patient was under ether the pin was found to be lying transverse and some distance above the inner orifice of the urethra. Previous to any examination the vagina was washed out, and prior to attempting to remove the pin the bladder was injected with water. The pin was caught and withdrawn. There was a very slight amount of blood in the urine that day, none afterwards, but the urine was turbid. On the fifth day the patient had a severe rigor and also pyelitis of both kidneys. Cause not quite certain, as temperature and pulse had been perfect, unless it was due to cold, as the patient had the day previously been sitting up in bed at an open window, without much covering. Symptoms gradually subsided, and the patient made a perfect recovery.—Dr. MORE MADDEN was certain that the Academy would appreciate the intent of Dr. Lane's communication, both as regards the comparative rarity of the accident described and the efficacy of the treatment adopted in the case just referred to. The bladder has in many instances been found to be the receptacle for a most extraordinary and heterogeneous assortment of misplaced articles, an occurrence of which several instances were long since related by the late Sir Benjamin Brodie,[1] as well as by Sir Philip Crampton, and more recently by Dr. Barton of Dublin.

Two Cases of Cæsarean Section.—Dr. SMYLY exhibited two patients upon whom he had performed Cæsarean section in the Rotunda Hospital. Both cases presented an extreme degree of pelvic deformity, and the birth of a living child by any other method than abdominal section would have been impossible. One case was a well-marked example of a rare deformity the result of a kyphosis in the lower lumbar and upper sacral regions of the spine, in which the narrowing was most marked in the transverse diameters, and especially at the pelvic outlet, and the other was an example of the generally contracted flat rachitic pelvis, in which the narrowing was most marked in the conjugate diameters, and especially at the pelvic brim.—Dr. MORE MADDEN pointed out that five-and-twenty years ago craniotomy was invariably resorted to in those cases of difficult or obstructed labour in which a living child might now be delivered from a living mother with safety to both. Dr. Murdoch Cameron of Glasgow, as well as Dr. Smyly and others, had abundantly demonstrated the possibility, and with due precautions the safety in proper cases, of the Cæsarean section. It was a great satisfaction to him to find that most of the leading obstetricians of the present day now probably agreed that child-destroying operations should be eliminated from midwifery practice, and that the only question in extreme cases of difficult labour should be which one of the two suggested child-saving operations—viz., Cæsarean section or Porro's operation—should be resorted to.

Dystocia due to a Cyst in the Liver of a Fœtus.—Dr. BAGOT read a paper under the above title. He considered the case of extreme interest from a pathological as well as from an obstetrical point of view. Records of cases where congenital cysts of any size had been found in the liver were very rare, as were also records of such, or indeed any, tumour of the fœtal liver causing dystocia. Dr. Bagot had been able to find only four cases, besides that recorded by Witzel, where dystocia had been caused by any form of liver tumour—viz.: (1) Haase (N. Z. xi., 262); (2) Müller (Hohl., p. 286); (3) Naggereth (Deutsche Klinik, 1854, No. 44; Wochenschr., iv., 458); (4) Schlesinger (Hohl., p. 289). The first three, according to Winchel, "resolve themselves into either hepatic physconia or a lymphatic tumour of the liver." The tumour in Naggereth's case was a carcinoma.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

AT the meeting on Friday, Jan. 8th, 1892 (Mr. Roberts, President, in the chair), Dr. DUNDAS GRANT gave a demonstration on several New Instruments used in the Treatment of Ear, Throat, and Nose Diseases. Amongst others he exhibited and described his Eustachian self-inflater, a safe endo-laryngeal forceps, and an apparatus for exploration of the antrum of Highmore.—The President; Drs. MacGavin, Tayler, Wainewright, and Clarke joined in the discussion which followed.

Reviews and Notices of Books.

Colour-blindness and Colour Perception. By F. W. EDRIDGE-GREEN. With Three Coloured Plates. Pp. 311. (Vol. LXXI. of the International Scientific Series.) London: Kegan Paul. 1891.

IN this work Dr. Edridge-Green presents to the reader the existing state of our knowledge of that defect of vision which consists in imperfect perception of colour, based on personal examination of 116 cases of colour-blindness and of all accessible recorded cases. After a short introductory section on the physical basis of colour, he gives an explanation of the terms he employs in the subsequent chapters. The most important of these is the term "psycho-physical unit," by which he means the recognition of distinct differences between different objects, and therefore in this case the perception of the several colours that an observer is capable of recognising in the solar spectrum. This number is found to vary; most observers can distinguish six units of colour—red, orange, yellow, green, blue, and violet; whilst some, like Newton, see seven, indigo being introduced between blue and violet. Latterly it appears some writers on colour have demurred to the insertion of indigo, and especially to its insertion between blue and violet. If a "six-unit" were asked to make seven colours, he would add greenish-yellow to the list. It has also been pointed out that indigo is a green-blue and not a violet-blue, and therefore could not be placed between the blue and the violet. He considers that impressions of sight may be divided into four sets—those of colour, form, size, and shade. We should be inclined to add a fifth, movement. In accordance with the theory of psycho-physical perception Dr. Edridge-Green states that the normal sighted will perceive any mixture of colours as a unit, a modified unit, or as white. It is not, therefore, surprising that the mixture of two colours representing the whole of the spectrum should make white. "The complementary of any colour can be obtained by the subtraction of the colour itself from white light. It therefore follows that the complementary of any colour consists of a mixture of the remaining rays of the spectrum." He gives the following list of true spectral complementaries: red, blue-green; orange, green-blue; yellow, blue; yellow-green, violet; green, rose.

In regard to the prevalence of colour-blindness, the results of Dr. Edridge-Green's observations give a rather higher percentage than those of other inquirers, with the exception of Dr. Wilson, for he finds the percentage of the two-unit to be about 2, of the three-unit about 1 5, and the percentage of the four-unit about 3. But as the four- and five-unit are, for all practical purposes, normal sighted, he does not include them, though they have really diminished colour perception. By the ordinarily used lists about one woman in 2000 is colour-blind. It is a rather more common defect in the uneducated than in the educated, and it is interesting to note that the author has found more colour-blind persons amongst musicians than in any other class or profession. He

Digitized by Google

holds the chief causes of colour-blindness to be diminution in the number of psycho-physical colour units and shortening o one or both ends of the spectrum; and whilst he proposes to name the normal sighted hexachromic, he terms those who are colour-blind from the former cause pentachromic, tetrachromic, trichromic, and so on, according to the number of the colour units they are capable of perceiving. A considerable section of the book is occupied with the classification of the colour-blind and with an account of the various methods that have been used and of those that should be used in testing colour-blindness.

Speaking of after-images, the account given of the after images seen after a momentary gaze at the sun corresponds with our experience in the succession of colours which become visible. First a positive yellow image of the sun is seen surrounded by pure green; the whole then changes into pure green, which becomes blue-green, then blue, then violet, and then very dark (black). A red element then comes in, and the after-image becomes purple, and then gradually fades away. He does not mention, however, the fact that when the image has nearly died away movement of the eye or pressure upon the globe causes its resuscitation to a condition of considerable brilliancy. Dr. Edridge-Green, believing, as above stated, that there is evidence to show that whilst most people see only six units of colour in the spectrum there is a class who see seven, constructed an ingenious test for the faculty in the following way. He painted a ground of prussian blue, and when the colour was dry put an after-tint of another colour over it, keeping a careful record of what he had done. In most instances he placed the second tint over only one half of the disc. On looking at these coloured discs he found that he was unable to tell, without referring to his note-book, the colour of the after-tint. He now took the discs to a well-known artist, but he failed to tell the colour of the after-tints. A pupil of his, however, a boy of fourteen, looked at the discs and told the colour of the after-tint correctly in each case. It is not surprising, then, that some artists render the tints of nature better than others; and it is somewhat amusing to read that in this case the boy apologised for seeing colours like this (his master being incredulous) by saying that he had something the matter with his eyes when he was a child. He raises some very strong objections both to the Young-Helmholtz theory of colour perception and to the theory of Hering.

Many points are noticed that we do not remember to have elsewhere seen. For instance, the author observes there is a variety of colour defect which is quite distinct from diminution in the number of the psycho-physical units—namely, a shortening of the spectrum,—and this may occur either for bright light or in the case of light of diminished intensity. A very common mistake, due to shortening of the red end of the spectrum, is the confusion of pink and blue. This Dr. Edridge-Green ingeniously explains in the following way. If a person with considerable shortening of the red end of the spectrum is shown a pink which is composed of red and violet the red rays are not perceived, and hence the pink appears as violet without a trace of red, and the pink is consequently matched with a violet or blue very much darker than itself. He has collected from various sources many instances of accidents at sea and on railways resulting from colour-blindness in captains and the drivers of engines; and there can be no doubt that the present mode of examination is unsatisfactory, and that before being promoted to such important and responsible posts the candidates should pass a skilled examiner well supplied with appropriate means of testing the existence of a normal power of discriminating colour.

OUR LIBRARY TABLE.

Practical Pathology and Morbid Histology.—By HENEAGE GIBBES, M.D., Professor of Pathology in the University of Michigan. Edinburgh and London: Young J. Pentland. 1891.—This is, in part, an expansion of the little work published by the author some years ago, and his acknowledged skill as a practical microscopist will doubtless give weight to his instructions. Indeed, in fulness of directions as to the modes of investigating morbid tissues the book leaves little to be desired. The ensuing chapters, which deal with morbid changes, seem, however, to lack something in respect both of detail and pathogeny. For instance, to ascribe the hyaline fibroid change often met with in the ovary to "chronic irritation of a neurotic character" is not only novel, but would require much cogent evidence before it could be accepted. The descriptions of tumours are for the most part brief and do not contain any new facts. The account of endocarditis is inadequate, and there does not seem to be sufficient justification for separating syphilitic endarteritis from endarteritis obliterans. Dr. Gibbes holds special views upon the lesions of acute tuberculosis, and maintains a distinction between "reticular miliary tuberculosis" and "disseminated catarrhal pneumonia," the latter consisting only of disintegrated products of inflammation, but containing numerous bacilli, the former yielding very few, if any, bacilli. The naked-eye characters of the two varieties are, he states, identical. He further seems to maintain a distinction between true tuberculosis of the lungs and pulmonary phthisis, and herein he occupies almost a solitary position among modern pathologists. The morbid lesions of the nervous system are but cursorily treated; but when we come once more to the technical part of his writing, as in the description of "photography with the microscope," we find the author at his best. He is most enthusiastic upon this latter subject, and the work itself is throughout profusely illustrated with reproductions of micro-photographs, some of which are admirable, others less clear. On the whole we may say that the practical histologist will gain much useful information from the book.

Die Protozoen als Krankheitserreger. Von Dr. L. PFEIFFER, Geh. Med.-Rath. und Vorstand des Grossh. Sachs. Impfinstituts in Weimar. Zweite sehr erweiterte Auflage. Jena: Gustav Fischer. 1891.—In November last, when we reviewed the first edition of this excellent work, we drew attention to the rapid strides that had been made in our knowledge of the protozoa related to diseased processes in man and animals. The appearance of a second edition of Pfeiffer's work so shortly after the first bears out most fully what we then stated, as the present edition is almost twice as large as its predecessor. The whole work is interesting, and an enormous number of new facts have been collected; but the second part relating to the occurrence of parasitic diseases of protozoan origin will have a special interest for our readers. Chapters on Malaria, on Vesicular Eruptions, and on Contagious Epithelioma and Darier's and Paget's Disease are especially interesting, and the short note on the Amœba Coli, which has been made familiar to English readers by Cunningham, Osler, and Simon, is also interesting. Even those who have read the first edition of this work will find it well worth their while to go through the second edition, as several mistakes have been corrected, and, as we have already stated, much new and important matter has been added.

Intubation of the Larynx. By JAMES B. BALL, M.D Lond., M.R C.P., Physician to the Department for Diseases of the Throat and Nose, and Senior Assistant Physician, West London Hospital. With Illustrations. London: H. K. Lewis. 1891.—This is in the main the

Digitized by Google

reprint of an article contributed in 1889 to a medical periodical. But it has been brought up to date by the addition of later statistical results and certain other details. It is a short account of the history of intubation, of the method of inserting and withdrawing the tubes, and of the results hitherto obtained by their use. Those unacquainted with this treatment will find in Dr. Ball's book a lucid description of it, unmarred by the exaggerations to which enthusiasm for their subject, especially when a "new" one, often leads authors.

Bibliographie der Klinischen Helminthologie: Heft I., Echinococcus Cysticus. Von Medicinalrath Dr. J. Ch. HUBER. Munchen: J. F. Lehmann. 1891.—This, apparently the first instalment of what should be an exceedingly useful series of bibliographical references, gives at a glance an index to the most important literature that has been published on hydatid cysts. First, there is a general list; then comes a classified list of the papers dealing with the echinococcus as it occurs in the different organs and systems of the body; then the distribution or geography is taken up to date; and, lastly, a list of 136 German dissertations, dating from 1808 to 1891, with a similar list of Paris theses—eighty-five in number—completes the work, which occupies about forty pages. It would be well if those working at other directions would take the same trouble to collect and arrange the literature of their subjects for future reference by other workers. This bibliography would have been still more valuable had a short abstract (two or three lines) of each paper been given along with some indication of the relative importance of the work.

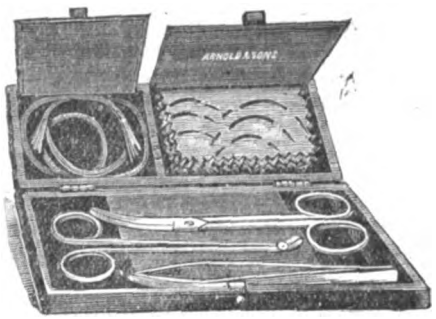
Clinical Lectures on Surgical Subjects delivered in University College Hospital. By CHRISTOPHER HEATH, Holme Professor of Clinical Surgery in University College, London. J. & A. Churchill. 1891.—These lectures have all been previously published in medical periodicals, and eight out of the total of seventeen have appeared in our columns. Our readers are well acquainted, therefore, with Mr. Heath's style as a lecturer. He is eminently simple and practical, and it is these features which have led to his success as a teacher, and they will commend these lectures to a large class of readers. Old University College men, in particular, will be very glad to have such a book as this to recall the lessons often impressed upon them by Mr. Heath.

Archives de Physiologie. Série 5, tome iv. No. 1. Janvier, 1892. E. Masson.—This number opens the new year well, containing a large number of articles, some of which are of considerable interest. Among these we may mention the following:—1. Inversion of the Blastodermic Laminæ, by M. H. Cristiani, which gives the results of investigations made upon more than 600 embryos of rats, showing that the effects of the inversion which occurs in the layers of the blastoderm in some rodents is not of any great importance in the development of these animals. 2. A curious paper on the Toxicity of the Urine of the Insane when injected into the veins of dogs and rabbits. 3. Mr. Roger gives the details of experiments, showing that the Liver is an important agent in preventing the Toxic Action of certain Drugs, as strychnine, as may be easily shown by the difference in the effect of that poison in animals possessing a liver as compared with those from which the liver has been removed. 4. M. Hénocque gives the results of his observations on the treatment of Phthisis by Injections of the fluid expressed from the Testes. 5. MM. Morat and Doyon give the results of their experiments to determine the Vaso-motor Nerves of the Eyes, which show that these nerves run exclusively in the cervico-thoracic sympathetic and in the fifth nerve. The great sympathetic plays in regard to the vessels of the fundus or posterior segment of the eye, the double part of constrictor and dilator. The fifth is the dilator of the vessels of both the anterior and posterior segments. 6. M. Gley supplies contributions on the Effects of Extirpation of the Thyroid in the Dog and in the Rabbit 7. MM. Wertheimer and Magnin give a paper on the Action of Ergotine and Ergotinin. 8. M. François-Franck shows a new Method of exposing and examining the Heart of Mammals. 9. Dr. Brown-Séquard shows that life can continue in certain regions of the spinal cord and in certain muscles andn erves for a considerable period after general death. 10. A Note on a Change hitherto unobserved in the Lens during Accommodation, by M. Tscherning.

Ophthalmic Charts. Devised by FRANK HAYDON, L.R.C.P. Published by Down Brothers, St. Thomas's-street, London, S.E.—These are charts of a convenient size (about three inches square), presenting a red ground with a white circle in the centre for the optic disc. By means of this anyone who is able to recognise the details of the fundus of the eye and has moderate skill in sketching can easily insert the vessels of the retina and depict any marked lesions of the retina or choroid. A legend below facilitates the recognition of the case by giving space for name, age, date, disease, vision R. and L., tension, and reading power. Another chart gives outline figures of the eye in full, in profile, and in section, which will save much trouble and at the same time prove very serviceable to the busy practitioner. We commend the charts to our readers.

Habit and Health: a Book of Golden Hints for Middle Age. Edited by GUY BEDDOES. London: Swan Sonnenschein and Co., Paternoster-square. 1890.—Though we cannot fix by any term of years the limit between youth and middle age, there comes a time in every life when, without apparent weakness, the abundant energies of the earlier period become set in a state of more moderate activity. There is good working power, and usually much to do, but a lessening of constitutional activity. The object of a series of hints on self-management at this critical period must commend itself to all thoughtful readers. Notwithstanding that a certain dryness attaches to this work in common with most others which are mere compilations of recorded opinion, it contains a good deal that is readable and instructive. More discrimination might, indeed, have been used in excluding views which have long since become antiquated; but one may still gather from this volume wise counsel as to personal guidance amid the work and worry of a busy life. Among other noteworthy quotations we may mention those from Abernethy and Sir Henry Thompson on diet, with some on exercise by Wilson Philip, as deserving of attention.

The *Veterinarian* for December contains reports of some of the papers which were read, and the discussions thereon, at the Seventh International Congress of Hygiene and Demography, a paper by Professor Walley, one by Mr. Gerald E. Griffin, D.V.S., on Porrigo (Texas Mange) in Horses, and an article on Tetanus by Dr. Claude D. Morris of New York. It also contains reports of the meetings of the Royal Agricultural Society of England, of the Central Veterinary Society, and the Scottish Metropolitan Veterinary Medical Society, before which Professor De Jong read a paper on Animal Parasites of the Skin.



SMALL-POX AT BATLEY.—Despite the precautions which the Sanitary Committee and officials are taking with respect to the small-pox outbreak in Batley, fresh cases occur daily, and the accommodation at the Isolation Hospital is now fully utilised. One death has occurred there since its opening, and another is reported to have taken place in High-street, making a total of fourteen. The majority of the cases are stated to be in the unvaccinated, and mainly those of children.

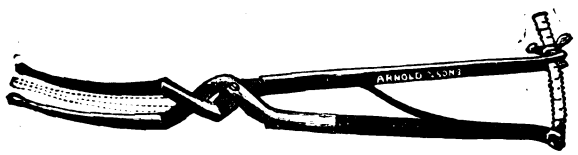
New Inventions.

AN IMMEDIATE PERINEORRHAPHY CASE.

THE accompanying illustration shows a case, made by Messrs. Arnold and Sons according to my design, containing all that is necessary for the suture, immediately after labour, of perineal ruptures. The contents are: 1. A supply of large full-curved needles of various sizes. In the circumstances under which the operation often has to be performed, unmounted needles appear to me to be more easily used than mounted needles, which need threading after passing.



2. Wells's needle-holder. This has no catch, and is the simplest and best for most purposes. 3. Curved scissors to trim off any loose shreds of tissue. 4. Dissecting forceps. 5. Supply of wire or gut suture. The above can of course be modified to suit individual preference, but probably the plan of combining in compact and portable form the requisites for the operation, and thus securing that they are always complete, clean, and ready for use, will be a convenience to many practitioners, and will encourage the more frequent performance of immediate perineorrhaphy.

Leeds. JOHN BENJ. HELLIER, M.D. Lond.

A NEW UTERINE DILATOR.

THE accompanying engraving represents a new dilator designed by me, on the principle of my phimosis dilator figured in THE LANCET. The advantages of the dilator are its simplicity of action and its applicability for different uses. Not only does it allow the cervical canal to be evenly dilated throughout its whole extent, but by an arrangement at the end of the handles of a rack and screw, working on a scale marked in eighths of an inch, the

operator may correctly estimate the amount of dilatation he is producing, and may also keep the blades fixed by the same rack and screw while he makes his application to the interior of the uterus. In many cases of abortion it is necessary to dilate the only partially opened os uteri, in order to abstract the ovum or placenta. In such cases the dilator is of particular use, as it can be employed to first dilate the os uteri and the cervical canal, and then as an ovum forceps, to remove the uterine contents. The instrument has been made by Messrs. Arnold and Sons.

Boscombe. FREDERICK GARDNER.

BRITISH MEDICAL BENEVOLENT FUND.

THE annual general meeting of subscribers to this Fund was held at the residence of the treasurer on Thursday, Jan. 14th, Sir James Paget, Bart., F.R.S., President, in the chair. Amongst the subscribers present were Drs. Baines, Steele, Ince, and Felce, and Messrs. Mould (chairman of committee), Field, Churchill, Page, with Dr. Sidney Phillips and Mr. Edward East (hon. secs.). In the absence of the treasurer the financial statement and the report of the committee were submitted to the meeting by the hon. secretaries. From these it appears that in administering the British Medical Benevolent Fund during the past year the committee have constantly kept in view the objects for which the Fund was founded—of affording immediate pecuniary relief to distressed qualified members of the medical profession, their widows or orphans, and of granting annuities to such after they have attained sixty years of age. The Fund has received during the year the sum of £4968 in legacies, together with income resulting from previous investments, and £3892 14*s.* 6*d.* subscriptions and donations. With regard to the legacies, the sum of £4968 includes the last instalment—£1450—of the Chapman bequest, making in all £14,750 from that estate; also £3500 from the estate of the late Dr. Marris Wilson, and £17 19*s.* 2*d.* from that of Miss M. A. Pretty. The income from dividends shows again a considerable increase owing to the large additions to capital made during the last three years. Subscriptions for 1891 have shown a marked increase, being £1312 2*s.* 1*d*, as compared with £1208 18*s.* 6*d.* in 1890, an increase of over £100. The donations, which stood at £576 in 1890, slightly exceeded that amount in 1891, being £580, independently of a generous donation of £2000 from "J. S.," bringing the total up to £2580. The total receipts, therefore, in subscriptions and donations was £3892 14*s.* 6*d.*, as compared with £1785 in 1890. The beneficiaires of the Fund have been relieved, as usual, either by grants or annuities. Grant department: The number relieved was 159, the same as in 1890, the grants varying in amount from £5 to £20, and, as in former years, these were in most cases distributed in instalments by honorary local secretaries and other members of the committee, or through the agency of the Cheque Bank, the amount distributed being £1768. Annuity Department: In this department £2000 of the donations, as well as £4871 received from legacies, were invested, and the special fund for raising £20 annuities to medical men to £26 was increased by the investment of £50 in Midland Debenture Stock. The sum of £1763 6*s.* 8*d.* was distributed in annuities to 99 recipients, these annuities being as usual paid monthly. There were altogether 25 new annuitants elected during 1891, 4 at £10 and 21 at £20 each, and two medical men were placed upon the special fund. Annuitants at the end of the year numbered 93. One honorary local secretary was elected during the year in place of Dr. Fernie—viz., Dr. Averill, for Macclesfield; and the services of gentlemen willing to act in that useful capacity would be welcomed by the committee. Of vice-presidents the committee have had to deplore the loss by death of Sir Prescott Hewett, Bart., F.R.C.S., and of Mr. John Morgan, F.R.C.S.; and Dr. Bissett Hawkins, F.R.S., and Mr. David Taylor were elected to fill the vacancies. Mr. J. H. Morgan, F.R.C.S., was added to the committee, the members of which, together with the officers, were re-elected. Votes of thanks to the chairman of committee, auditors, treasurer, and hon. secretaries, the medical press, and to Sir James Paget, the chairman, were accorded and suitably acknowledged. The committee would observe that the entire work of this charity is voluntary, only printing and stationery costing anything; so that, excepting collectors' commission, every penny subscribed is available for the purposes of the Fund; and they would earnestly solicit the attention of the profession to the work and invite subscriptions, which may be sent to any member of the committee, and especially to the honorary financial secretary, Sidney Phillips, M.D., F.R.C.P., 62, Upper Berkeley-street, W.

THE LANCET.

LONDON: SATURDAY, JANUARY 23, 1892.

THE great political event of the day in the politics of the world is the famine in Russia. There can scarcely be a doubt that the event threatens to be appalling. Out of it, if it progresses, we are condemned almost of necessity to experience one of two additional calamities—war or pestilence; nay, perhaps a combination of these lamentable evils. The immediate cause of the famine it is not easy to divine; the full extent of it is difficult to define; so many unsatisfactory and inextricable causes or descriptions have been stated, on what is called authority, but authority of little value. It is, however, a fact that, despite the domestic economy of the peasantry of Russia, and in most instances of the noble families, there has been a steady dearth of food. Before the war between Russia and our own country in combination with France, the surface of the Russian Empire embraced 1,675,492,948 acres of land, rather more than one-fifth of which was under cultivation. About 24,000,000 acres were private domains; 218,387,516 were devoted exclusively to arable purposes; 107,971,138 were pasture land; 393,277,413 acres were covered with forest wood, and 932,052,138 were waste. Deducting the waste and forest lands from the whole, there were left 350,163,397 acres of cultivated soil, which, on a uniform distribution to population, would have given a proportion of more than six acres and a half to each one of the 53,000,000 of the then existing inhabitants. From these resources it was calculated that the produce of the empire was sufficient to supply all the people with the elements of food that were just sufficient for life. There the produce ended; for beyond the production of food very little indeed was done with the soil. A few years before the war it seemed as if Russia were contemplating the opening up of her mineral resources, and a man of science from Russia, the Count ST. ALDEGONDE, who knew the then reigning Czar, came over to this country to see how we developed our mineral wealth, and sought interviews with some of our leading engineers in order to ascertain what help they could give towards realising the splendid conception. SOPWITH, one of our men of science whom the Count consulted—and a better authority he could not have selected,—was much taken with the design; he considered that in such vast tracts of country the most precious mineral wealth must lie concealed, especially in the southern districts, and he thought that the whole question of advancement of the Russian peasants lay in making them miners on their own soil rather than residents in Siberia.

Every historical student knows that this beneficent project was never carried out, but that instead the great empire was setting its teeth for war. Not to develop peace and plenty at home, but to try to seize plenty abroad by the instrumentality of an overwhelming armed force was the policy pursued—a policy as decisive as it was fatal. Within fifteen years the difficulty with the unspeakable Turk came again forward, followed by the Crimean campaign, the humiliation of Russia, the triumph of England and France, and a patched-up peace. From that moment the Russian peasant lost, in some degree, even the former quota of the miserable black bread on which he had previously held body and soul together. All heart for engineering enterprise failed, except when the manufacture of weapons of destruction was concerned. She fought again, and for once to conquer, but only to impoverish herself the more. We have known for some time past that her cargoes of grain as export produce have grown smaller and smaller; we have heard from travellers in her domain, like that bold and fine observer the Rev. Dr. LANSDELL, that, however fair her exterior, she was in danger on every hand; and now we realise where her chief danger lies,—not primarily, as many have supposed, in Nihilist conspiracies, nor in wars on foreign soil, but in plague, pestilence, and famine on Russian soil itself—famine set by Russian hands that might now have been opening the vast treasures which the soil only conceals, and by which, with less ambition for the conquest of men and more ambition for the conquest of nature, her Government might long ago have converted a starving people into one of the wealthiest and happiest on the face of the globe.

Let bygones be bygones; we are now in the presence of a great calamity, and it is our duty, as men of humanitarian science, to do all we can to enlighten everyone whom we are able to influence on a subject that must come home practically, to some extent, to everyone. The danger of famine is famine fever, and famine fever, when once it is established, is a disease which shows no respect to distinctions. It spreads from the famished to the unfamished. As we have seen it, famine fever is a special pestilence of the remittent type, very fatal, easily communicable, and running a course, when once it is lighted up, uninfluenced by any specific remedy. It is as if the starving people generated it, as the neglected occupants of the gaol, before the time of HOWARD, generated the malignant typhus which made the "Black Assize" and many more assizes equally black, the histories of which have never been told. It is a fever very unmanageable in respect to individual sufferers, and when it has gained its ground it is as unmanageable, in respect to its ravages, in communities. The grand sanitary manœuvre is to prevent its commencement. In the Irish famine we did not prevent its birth, and we know the cost that was paid for our negligence. In the cotton famine of Lancashire we succeeded in preventing its inception, and we have ever since felt the triumph of science in that success. We learned also in that triumph how comparatively easy a thing it is to accomplish success, even under great pressure. Whether the Russian authorities have the means at hand to follow our example let the special report we this day publish tell. The Russian peasant living on such bread as we have subjected to analysis and describe to-day must already be on the verge of starvation before his exposure to actual starvation begins. His tastes, moreover, are little cultivated for any new supplies that may be sent to him from abroad. These are ominous facts; but they should not stand in our way in the attempts to stop at its

Digitized by Google

beginning a disaster the end of which, if it be allowed to go on, must be perilous in these days of intercommunication to the whole world. How the assistance of this country can be best administered is a difficulty of supreme importance. Money we can raise; but money, like the bag of gold which the starving traveller found in the desert, hoping for his life-sake that the rich coins were dried nuts, may be more easily thrown away than usefully applied. For our part, we admit that at the present we do not see any method of application of means other than by the transportation of food. But what food can be sent to supplant the stuff we have analysed, and, in the face of the obstacles which lie in the way of distribution, how can the starving people be fed with what is offered to them?

THE severity and extent of the present outbreak of influenza are well calculated to excite apprehension, but to give way to unreasoning panic is foolish and reprehensible. Some of the comments made by irresponsible writers on the apparent impotence of medicine to allay this scourge seem almost akin to those ignorant outbursts of fury which in time of plague have led in some countries to the infliction of personal violence upon those engaged in caring for the sick. It is perhaps hard to maintain a philosophic calm when the people are perishing, presumably from "lack of knowledge," but at least credit should be given to the guardians of the public health for sparing no endeavour to understand the true nature of the malady that has so many singular features and visits the globe at such rare intervals. When the Italians gave the name "influenza" to the affection they did so in the belief that its visitations were connected with astral conditions, and doubtless at the time such an explanation was deemed sufficient. At any rate, it relieved men from the labour of seeking for mundane sources of origin. And it is possible that if some ingenious philosopher could formulate a theory of the disease somewhat more in harmony with science, and would adhere to it as the true and only explanation, many would feel satisfied with his explanation without further proof. Such a mode of solving pathological problems would not, however, be in accord with the spirit of modern research. The inquiry into the nature of so rare and remarkable a malady is complicated by so many circumstances that it requires a patience which is not invariably shown by those who clamour for more knowledge. The latest bacteriological investigations by Drs. PFEIFFER, KITASATO, and CANON have led to the discovery in the expectoration and in the blood of influenza patients of a hitherto undescribed microbe of very minute size and special properties, which so far has responded to the tests requisite to determine the pathogenic nature of such organisms, and has been successfully cultivated in nutrient media. The importance of this discovery is heightened by the now fairly general belief in the infectiousness of influenza.

Still it must not be forgotten that until the present pandemic, which began in the autumn of 1889, opinion was not only much divided as to the contagiousness of the disease, but rather, we would say, predominantly opposed to this view of its nature. Miasm rather than contagion, certain obscure atmospheric agencies rather than direct transmission of germs from individual to individual, were held to be most fitting to explain the remarkable phenomena it exhibits. The extreme rapidity with which the malady spreads over the surface of the globe, the simultaneity of outbreaks in widely separated countries, the similar general incidence upon large numbers of people at one and the same time, these and many other considerations weighed in favour of its non-contagiousness. Nor is it possible to entirely divest the mind of the idea that the disease is spread in other ways than by direct or indirect infection, although Dr. SISLEY—who is a leading exponent of the infectious doctrine—considers that general susceptibility or vulnerability, added to marked brevity of an incubation period, can explain all these apparent anomalies. Whether it be miasmatic or not, it is, however, indubitably infectious, and the resolution passed at the recent meeting of the Society of Medical Officers of Health conveyed this opinion in an authoritative manner, being thereby in harmony with the conclusion arrived at by Dr. PARSONS in his inquiry on behalf of the Local Government Board, and that which is said to have been reached by the German Collective Investigation Committee. It may therefore be taken as a postulate that one, if not the sole, mode of spread of influenza is by infection. What, then, is the logical outcome of such an admission? Clearly, some would say—and Dr. SISLEY himself advocates this in his interesting monograph—schedule the disease in the Public Health and Notification of Diseases Acts, and enforce the provisions of those Acts with all the rigour that the law demands. Unfortunately, from the very nature of the disease, the spread of influenza is not likely to be controlled by such a step. The meshes of the Act—although sufficient, doubtless, to arrest the progress of epidemics of other known contagious disorders—are not fine enough to retain within them so subtle a malady as this. It will elude them as easily as water will escape from a sieve; and it needs no extraordinary foresight to see that were the country to act, in respect to influenza, on the principles laid down in those enactments, the result would be a costly and disheartening failure. On a smaller scale, even, much disappointment might attend such isolation and measures of disinfection as can be practised in a household, and the adoption of which may be recommended. The "shortness of the period of incubation," adduced by Dr. SISLEY as one reason for its rapid diffusion, may evince itself in successive attacks of other members of the family, and render all such precautions of no avail, except as protecting new comers to the infected house. In his excellent exposition of the legislation in force in this country on infective diseases, in the paper read before the Society of Medical Officers of Health (*vide The Times*, Jan. 20th), Dr. SISLEY considers that had influenza been declared among the scheduled diseases before the prevailing outbreak much might have been done to limit its spread; but he also shows plainly that in the midst of an epidemic the time involved in the legal formalities of placing it on the list would render it practically impossible for the sanitary authorities to exercise any adequate influence on the spread of the disease. Dr. SISLEY is far more confident than at present we feel that we can be of the possibility of coping with influenza by prophylactic measures.

Digitized by Google

Although, then, there may be legitimate ground for disputing the efficacy of the ordinary measures of prophylaxis, there is a practical consensus of opinion as to the general lines of treatment to be adopted in the developed attack. There can be no question as to the advantage of having prompt recourse to rest in bed and a persevering administration of easily assimilable food, together with such special remedies as may be called for by the type of the disorder. Every practitioner knows that the manifestations of influenza are by no means uniform, that in some the headache, pains, and prostration, in others gastric or pulmonary catarrh, predominate, and he has to regulate his choice of remedies accordingly. Few are prepared to admit that, even with the adoption of all precautions, it is possible to ward off the supervention of severe bronchitis or pneumonia, which carries off so many of the weakly and the aged, or to prevent the protracted convalescence and the nervous sequelæ that characterise a certain number of cases. When, however, we attempt to realise the extent to which influenza prevails, and estimate its gravity in proportion to its morbidity, even the long list of fatalities dwindles to almost insignificant proportions. Still this is but small consolation, and the demand for some truly specific or antidotal remedy is perhaps natural. Many such have been introduced—some, to be sure, with little reason, and all based more or less upon theoretical considerations. There is, however, one remedy which, from its simplicity and from the very confident opinion expressed by its introducer, may be singled out, in order, if possible, to get some more general opinion as to its merits. We refer to the use of large and repeated doses (thirty grains every two or three hours of potassium bicarbonate, which Mr. CRERAR of Maryport introduced to the notice of his fellow practitioners in an address he delivered as president of the Border Counties Branch of the British Medical Association (and which appeared in abstract in these pages on Dec. 19th, 1891). We need not concern ourselves with the somewhat strained analogies and arguments adduced by Mr. CRERAR in that paper, or dwell on the fact that it is not possible from his address to perceive why he should have come to the conclusion that the influenza poison could be neutralised by increasing the alkalinity of the blood. We may fail to be convinced of his logic, and yet not refuse to accept his facts; and the evident sincerity of his statements, which, in a paper he has just forwarded to us, are supported by the experience of others, and particularly by the personal testimony of a well-known teacher in Edinburgh University, together with the results of the treatment in the wards of the Edinburgh Infirmary, seem to warrant some attention being paid to them. It is not necessary to give the text of this paper, which mainly consists in the citation of such testimony, but in justice to its author we may quote his conclusions as to the advantages of the method. They are:—

"1. If used before the attack it prevents the disease. 2. It destroys the power of the disease within twenty-four hours, generally within four or six hours. 3. The strength is conserved, and the convalescence is short and satisfactory. 4. Sequelæ are conspicuous by their absence. 5. The death-rate is reduced to a minimum. I have not had any death in more than one thousand cases. 6. It has more power over influenza than I have ever seen exerted by any method of treatment over any other disease, and I have had an extensive practice for upwards of a quarter of a century. 7. If adopted by the whole profession it would make influenza non-existent in one week. 8. It rests upon a sound scientific foundation."

The last two conclusions may be open to question, but the preceding are statements which no medical practitioner of standing would venture to put forward without good cause. Therefore, without in any way desiring to bias opinion, we have, after due consideration, deemed it only right to call attention to these statements in order that they may be put to the test. No doubt one's first impulse is towards incredulity, but *primâ facie* it can hardly be asserted that the method is unreasonable, although the administration of such large doses of a salt that has undoubtedly a depressing action on the circulation is surely a step to be taken with circumspection and care, especially in a disease so characterised by depression as influenza.

IT is now nearly nine years since the operations of the Contagious Diseases Acts were suspended in their most important feature, and seven years since they were wholly repealed. A sufficient interval has therefore elapsed to enable both their supporters and opponents to judge how far their action was justified. In THE LANCET of Feb. 7th and 14th, 1891, the results were given so far as regarded the reduction of disease in the army and navy, and, so far as could be ascertained from death statistics, among the civil population. These showed that, making every reasonable deduction for increase or decrease accountable for in other ways, or for fluctuations which affected all the military stations whether protected or unprotected, the reduction of disease at the fourteen protected stations was from the first persistently and markedly lower than in the other stations, whether the ratio of reduction was compared with that of fourteen unprotected stations selected for the purpose of comparison or with that of all the stations never under the Acts. In the naval stations the reduction was well marked in the ports protected by the Acts as compared with those which were not protected. With regard to the civil population, there was a remarkable diminution in the ratio of deaths from syphilis in those districts of the Registrar-General which contained the protected stations. Since the Acts were repealed all this has changed, and the diseases which these Acts were passed to prevent have reverted to the extent and severity which they showed prior to the passing of the Acts. But this reduction of disease, though it accomplished the purpose for which the Acts were passed, though of great importance to all interested in the wellbeing of the army and navy and of the State at large, is by no means the only good effects of these much-maligned and now repealed Acts. As one evil leads to another, so does an honest effort act in its good results far beyond its original designs. The object of those by whose efforts the Acts were passed was the honest desire to reduce the amount of venereal, and particularly of syphilitic, diseases, which then prevailed to an extent which a Select Committee of the House of Commons described as "appalling." This strong expression was not applied to any of the other diseases from which soldiers and sailors suffer in common with civilians,

Digitized by Google

from which it may be concluded that syphilitic diseases had gradually increased to such an extent and severity as to seriously alarm the authorities. Hence followed the Select Committee of the House of Commons in 1862, the first Contagious Diseases Act of 1864, the appointment in that year of the Select Committee of Physicians and Surgeons, of which the late Mr. SKEY was chairman, and later on the amended Acts of 1866 and 1869, and the Royal Commission of 1870.

The women who then surrounded the camps and abounded in the naval seaports were described in the report of the Royal Commission as "miserable creatures, who were mere masses of rottenness and vehicles of disease;" while one of the witnesses described the "soldiers' women" admitted into one of the metropolitan workhouses as "a very low, dirty class, the shame of humanity." It is not surprising, therefore, that the first Act contemplated rather the prevention of disease among them than their reclamation. But this omission was only temporary. These women, brought, some from their miserable dwellings and others who had no homes at all from their haunts, to hospitals where they were cared for and kindly treated, were first humanised, and thus rendered capable of receiving the benefit of religious influences. Their reclamation soon became a recognised part of the system, and the influence brought to bear upon these women by the chaplains, the matrons, and the medical officers was most successful. The Acts were not only successful directly in preventing, and reducing disease, but also, indirectly, in reclaiming from a vicious life women whom society had left to perish, and whom even philanthropy had failed to reach.

Those, therefore, who have supported these Acts through evil report and good report may very fairly ask their opponents, You have closed ten Government lock hospitals; have you provided others in their stead? You have disestablished the chaplains, the matrons, and the medical officers, who were instrumental in reclaiming so many of these poor outcasts; have you provided any substitute for these? Is the "social evil" less rife in and around Aldershot, Chatham, Portsmouth, Plymouth, Cork, and the Curragh since the Acts were repealed? Is it better or worse in London, Birmingham, Manchester, or Liverpool, where the Acts have never been applied?

As the recent case of the Spinning House at Cambridge is still *sub judice*, any comment would be improper. But let it be supposed that a serious and earnest effort were made to prevent or diminish venereal diseases in the metropolis or any large centre, how could this be accomplished. There can be no doubt that these diseases are largely propagated by those women who make prostitution their means of livelihood. Many of these women, notably those of the lowest class, might still be called the shame of humanity. Would it not be to them a humane act to reach them by the aid of some machinery, whether by police or other aid, to ascertain by medical examination whether they are or are not diseased, to have the diseased conveyed to hospital and detained there till their maladies are cured, and to subject them to moral and religious influences? That some would be reclaimed cannot be doubted; that others would return to their old life is too probable. But there would be this difference between the proposed new and the present system, that at least something had been done to benefit their bodies directly, and their souls indirectly. THE LANCET has so repeatedly urged the importance of chastity in men, that the insinuation of wishing to make vice safe is one which, if raised, can be disregarded. The social evil has always existed, and it is to be feared will exist, so long as poor human nature remains frail and sinful. Much, however, might be done to diminish its worst features without in the slightest degree encouragin immorality.

Annotations.

"Ne quid nimis."

THE INTERNATIONAL SANITARY CONFERENCE AND THE SUEZ CANAL.

IT is not yet clear what will be the outcome of the International Sanitary Conference at Venice. A great deal of misconception appears to exist in regard to the subject of epidemic cholera. The current doctrine seems to be that India is its great home and manufactory, and the starting place of European epidemics, and that a system of maritime quarantine is consequently especially necessary and easy of application in the case of India, seeing that the Suez Canal is the channel of communication between that country and Europe. Now, what are the facts? A paper written by Dr. W. J. Simpson, the health officer at Calcutta, for the International Hygienic Congress of 1891, on "Maritime Quarantine and Sanitation in relation to Cholera," which has appeared in the *Indian Medical Gazette* for December last, puts these very clearly. Dr. Simpson fully believes that cholera, under certain conditions, is a communicable disease, and that its history in Europe and America shows that it has been carried in ships; but he nevertheless contends that it has never been carried from India to Europe by shipping, and that the chances against its being so conveyed to Europe through the Suez Canal are very slight indeed, for the simple reason that the population which is chiefly affected by epidemic cholera in India never travel by ships. The fact is that the religious and social conditions prevailing among the inhabitants of India enforce upon them a far more rigorous system than is imposed by any methods of quarantine. The native population of India mainly consists of persons of the Hindoo and Mussulman faiths, and it is among these that cholera epidemics occur. Now the Hindoo is prohibited by his religion from making a sea voyage to Europe. He would be excommunicated and cut off from Hindoo society in its social, religious, and political aspects. As regards the Mahomedans, on the other hand, they are not a migratory or maritime race and as a matter of fact are, as far as regards trade, as isolated by sea from Europe as the Hindoos who never stir from India. It follows therefore that the risk of cholera being imported from India into Europe is practically confined to the Europeans—civil and military—among whom cholera rarely prevails. Cases of cholera, no doubt, do occur, however, among the passengers by troopships and steamers; but the disease commonly ceases before the ships reach Suez; and, anyway, there is no record of an epidemic or outbreak of cholera in Europe having been traced back to India *viâ* the Suez Canal. That is not the way by which the disease has reached Egypt or Europe. On the contrary, there is every reason to believe that Dr. Simpson is right when he says we must not look to India, but to Mecca, as the place whence, and to the pilgrims assembling there annually from Europe, Asia, and Africa, by land and by sea, as the chan-

Digitized by Google

nels by which cholera is transmitted, and apply our sanitary regulations and precautions there. Be this as it may, it still seems to us that on the grounds of common sense and practicability it would be safer to send a cholera infected vessel straight through the canal to her destination without touching anywhere than to detain her at Suez in quarantine, for the disinfection of personal linen, &c., under conditions that would be likely to augment the risk of an outbreak rather than otherwise. It is assumed, of course, that the ships would pass through the Suez Canal as if it were an arm of the sea, and without any communication whatever with the shore. As regards Malta and Gibraltar, the fear lest the commercial relations of these places with other maritime countries would be jeopardised, to say nothing of the timidity of their native populations, would probably lead to all the cholera-infected vessels being put in quarantine at those stations.

HOW TO IMPROVE THE POSITION OF THE PROFESSION.

DR. ORLANDO JONES, in his presidential address to the Harrogate Medical Society, took for his subject the Possibility of Improving the Position of the Medical Profession. He infers from the writings of Pliny, the medical learning of the Druids, and from those of Ptolemy that their wealth was equal to their learning. Such being the honoured and happy case of the ancient representatives of medicine, he argues that it should not be otherwise with its present practitioners. He does not seem to look for any amelioration in the position of the profession by attacking the Council of the Royal College of Surgeons, or by a mere increase in the direct representation of the profession in the Medical Council. These are his negative views. The first of his positive suggestions for improving the tone of the profession is the introduction of a law enforcing at least one year's apprenticeship before the commencement of medical study; the second is the formation of a fund for the benefit of the profession, encouraging thrift among the active and giving help to the less fortunate. There is something to be said for both suggestions, but we confess to thinking them entirely inadequate as the sole levers by which the positive tone and power of the profession are to be raised.

A FRAUDULENT UNDERTAKER.

IT is much to the credit of the large class of men and women who conduct funerals, and have many opportunities of resorting to irregular practices for the sake of gain, that so comparatively few charges are brought against them. The few irregularities which do occur generally come to light sooner or later, and the exposure, together with the fine or imprisonment which follows, must mean ruin to the prisoner so far as his calling is concerned. The most recent case is that of an undertaker who was summoned before Mr. Baggallay at the West Ham Police-court, at the instance of the local superintendent registrar of births and deaths, for burying the body of a child aged ten days in the coffin containing the body of another child sixteen days old. Mr. Lynch, the barrister, who prosecuted, described the case as a cruel fraud upon poor people, and the worthy magistrate emphasised this even more strongly. It appeared that a woman named Healey lost her child on Oct. 8th last. It was only ten days old, and its mother, who was still ill, saw the body of the child placed in the coffin, which was brought to the house, screwed down, and taken away. The birth and death were registered, and the burial order was sent to the defendant's place of business, and on the 10th he sent her word that the child had been buried in the East London Cemetery, giving her the number of the grave. Later on Mrs. Healey went to the cemetery to visit the grave of her child, and not being able to find the number of the grave she communicated the fact to the cemetery authorities, who subsequently found that the body of Mrs. Healey's child had been buried with a child named Walker. The defendant had therefore defrauded the cemetery authorities and acted in contravention of the Registration Act, which requires the burial order to be delivered to the cemetery authorities. But this was not all, since in this as in similar cases one fraud leads to another. The child Walker being sixteen days old, the defendant had altered the figures in the burial order to eleven days, his object being to save 2*s.* 6*d.*—the difference between a child under twelve days and above that age. The defendant wanted to hush up the matter by paying a few shillings, and when this was refused he declined to say in which of three cemeteries the child's body had been buried. He also said that he had done the same thing many times, and that all undertakers did it, which we hope and believe is untrue. He was fined £10, with £2 14*s.* costs, with the alternative of two months' imprisonment. The fine was paid. Some years ago the bodies of four newly born infants were found in the coffin of an adult, and it is chiefly with newly-born children, stillborn or surviving their births from a few minutes to a few weeks, that these frauds and breaches of the Act occur. A sliding scale of fees is indispensable, but it would be more reasonable if it referred rather to the space occupied by the body than to its age. To poor people it must seem inexplicable why they should have to pay what to them is a very serious sum because a child lived a few minutes or because it died on the twelfth instead of the eleventh day after birth. Many a stillborn infant weighs and measures much more than a prematurely deceased infant, and yet the fees for the latter are often double those of the former. Perhaps some scheme may be adopted which will not hold out inducements for fraud in the burial of infants, and appear less arbitrary to those upon whom the expense falls.

THE CENTRE FOR HEARING.

A CASE of no little interest and importance in this connexion is recorded by Dr. C. K. Mills in the current number of *Brain*. The patient, a woman of forty-six, was admitted to hospital in August, 1891. Her history made it probable that she had suffered from specific disease. She was right-handed. Fifteen years before she had a "stroke," which left her word-deaf, but not paralysed. She could hear musical and other sounds, but she could not understand words; yet she could apparently read and understand a paper, although in an attempt at reading aloud she made a jumble of the words, and a similar imperfection was present during ordinary attempts at speaking. She was able to write, but wrote wrong words. Six years later she had another stroke affecting the left side of the body, and leaving her partially paralysed on that side, and then her hearing was much impaired, so that there was not only word-deafness, but deafness also for ordinary sounds. Her condition, when examined by Dr. Mills, was one of almost complete helplessness. It was impossible to make her understand what was said to her, and after repeated tests the conclusion was come to that she was totally deaf. She died of exhaustion, and at the necropsy the left superior temporal convolution was found to be much atrophied, except anteriorly. In the posterior fourth of the second temporal convolution and the parallel fissure was a depression or cavity, at the bottom of which was a small mass of shrivelled tissue, which was regarded by Dr. Mills as the remains of an old patch of softening. The rest of the temporal lobe was normal, but there was a considerable amount of atrophy around the ascending branch of the Sylvian fissure and the bases of the two central convolutions, as well as in the hinder part of the third frontal. In the right hemisphere was an old haemorrhagic cyst, completely destroying the first and almost

Digitized by Google

completely the second temporal gyrus, the island of Reil, and the convolutions behind, as well as part of the ascending convolutions and of the central substance. The auditory nerves were atrophied, and the striæ acousticæ are said to have been invisible to the naked eye. From this case Dr. Mills thinks he is justified in contending that the centre for word hearing is situated in the hinder thirds of the first and second temporal convolutions, and is possibly restricted to the second, and that although the auditory cerebral arrangements have their chief development in the left temporal lobe, destruction of the opposite centre is necessary in order to abolish hearing entirely. Several minor conclusions are also drawn, but the above are the most obvious.

NEW WATER-SUPPLY FOR DANBURY.

AN excellent water-supply has been provided for Danbury in Essex, and the arrangements have been ingeniously and skilfully carried out. Spring-water, certified as pure by Dr. Thresh, is first collected in a reservoir, and it is then passed down to a hydraulic ram, by means of which it is lifted 180 feet through a rising main of about one mile in length. Thus, by gravitation, the inhabitants are supplied with some twenty-five gallons a head per day of wholesome water at a cost which will be entirely covered by a small and reasonable water-charge. It is stated that there is not another ram in England working with a 27 feet head and throwing water to such a height as has been effected with success at Danbury. The scheme is, from this point of view, worthy of the attention of the sanitary authorities of rural and small urban districts.

EXPERIMENTS WITH THE PNEUMOCOCCUS.

AT the present time, when pneumonia is exceptionally prevalent, it may be well to recall the investigations conducted last year by Drs. G. and F. Klemperer, and published in the *Berliner Klin. Wochenschrift*[1] in August last. They then detailed experiments, the practical outcome of which may possibly be of real therapeutic importance. It is known that in most cases pneumonia, after having during from five to seven days caused grave general symptoms, terminates abruptly by crisis. At this period there has been little or no change in the state of the lungs, which still remain infiltrated with fibrinous exudation, or in the properties of the pneumococci, which are found in great numbers in the sputa and retain all their virulence. On what, then, does the pneumonic crisis depend? Only one explanation seems possible: the crisis is due to the products of the organisms, which, by their accumulation, modify the soil on which the microbes develop. In their experiments made on rabbits, the investigators observed that any nutritive substance which had served as a culture medium for the pneumococci, even if it had been separated from the microbes by filtration, conferred on the animal immunity against the pneumonic infection. They next proved experimentally that the blood serum of a rabbit "vaccinated" against the pneumococcus may cure an animal infected with pneumonia. An intravenous injection of eight cubic centimetres of serum of an animal rendered refractory, practised twenty-four hours after the infection, produces a gradual fall in the febrile temperature, and hastens the recovery of the animal. In another series of researches, devoted to the study of the cause of the remedial action of the serum of inoculated animals, the same observers found that the pneumococcus, when introduced into the body of an animal, gives rise to the production of a "pneumotoxine," which may be isolated. This pneumotoxine produces a febrile reaction of several days' duration, after which they have noted in the fluids of the animal another substance, "anti-pneumotoxine," which has the power of neutralising pneumotoxine. The blood serum of an animal on which immunity has been conferred contains anti-pneumotoxine, and it is this which seems to forward the recovery from the pneumonic infection. In the blood serum of patients affected with croupous pneumonia, they have also found pneumotoxine and anti-pneumotoxine, the former chiefly during the febrile period of the disease, the latter after the crisis. They also claim to have treated successfully rabbits suffering from pneumonia by injecting into these animals blood serum taken from a pneumonic patient after the crisis. Being assured by experiments made on themselves that man may support with impunity and without any local and general reaction injections of the serum of animals rendered refractory to Fraenkel's pneumococcus, the investigators treated six patients affected with pneumonia. Although the number treated was small, the result has been very encouraging. In fact, in all these patients a hypodermic injection of from four to six cubic centimetres of serum was followed at the end of from six to twelve hours by a considerable fall in the temperature, with slowing of the pulse and respiration. These observations are especially noteworthy as confirming those made by Emmerich and Fowitzky, who claim that they have conferred immunity on the rabbit by means of hypodermic injections of attenuated cultures of the pneumococcus; but this immunity, they say, is incomplete. On rabbits infected by pneumococci, on the other hand, full immunity is obtained by intravenous injections of a culture having its entire virulence, but largely diluted. The liquid obtained by crushing the organs of an animal thus rendered refractory exercises on the pneumonic infection a sure remedial action when it is injected under the skin or into the abdominal cavity, and especially when it is thrown into the veins of the infected animal.

[1] Abstract in the Boston Medical and Surgical Journal, Nov. 12th, 1891.

THE MILITARY HOSPITALS IN UPPER EGYPT.

AT the conclusion of his recent tour of inspection in Upper Egypt, Major-General Walker, commanding the army of occupation, directed a letter to be written to the officer commanding the frontier field force in which General Walker, among other subjects connected with his inspection, referred to the condition of the hospitals with which, he said, he was particularly pleased.

THE PASTEUR INSTITUTE AT MILAN.

WE have before us the committee's report of the working of this institution—"Istituto Antirabico Milanese," as it is officially called—for the two years that have elapsed since its foundation, and a most interesting document it is. Financially, the Institute is in a flourishing condition, thanks mainly to the liberality of local business houses, seconded by careful management. Therapeutically it has more than justified its establishment. Dr. Remo Segré, its director, having passed in review the various methods of combating the canine virus in the human subject, decides most emphatically in favour of that of Pasteur. His statistics, checked in every possible way, certainly bear out his decision—the one modification he ventures to make on the method of his master being as to the dose of the matter inoculated. This he would certainly increase, even in the case of children. Dr. Segré uses a syringe of two grammes and a half, and employs an entire centimetre of marrow for each patient. He obtains an emulsion much denser, and therefore richer in the remedial principle. "It is notorious," he adds, "that children form the larger contingent of our patients and have a greater receptivity for the canine virus than adults. A more energetic action of the remedy being therefore required, he gives the child as large a dose as the grown man. On the system of the parent Institute at Paris,

Digitized by Google

he divides the patients under treatment into four categories. The first, in his report, includes 108 persons bitten by hydrophobic animals whose rabies was confirmed by experiment in the laboratory, or bitten by animals whose bite was followed by death from hydrophobia in other persons. In this category, out of 108, there were but two deaths. The second category comprises 121 cases of persons bitten by animals whose rabies was tested and reported by a medical man or a veterinary surgeon. In this again, out of the 121, the deaths were only two. The third category contains nine doubtful cases. In this no death occurred. The fourth and last category is made up of cases "remanded"—that is, of persons bitten by dogs or animals, but in whose cases the evidence of being bitten was not sufficiently complete to justify their being subjected to the Pasteur treatment. This, of course, includes no deaths in Dr. Segré's report. He claims a lower percentage of mortality than can be shown by any other Pasteur Institute on the Continent, and some of his remarks are of interest as evincing the care he bestows on the subjects brought under treatment. Having shown that male cases are more numerous than female, and that children are more often bitten than adults, he observes that the more the bites on a patient and the more various the parts bitten, the more probability is there that the animal is hydrophobic. With regard to the four deaths that occurred after treatment, he says that cauterisation had been practised on all, and without loss of time; with the actual cautery, moreover, which is considered the best in such lesions. This fact of the greater mortality occurring among the cauterised is in absolute keeping with the statistics of the Pasteur Institute at Paris. Dr. Segré adds that a prompt cauterisation, made within half an hour after the bite, has always a certain value, but it must be a liberal cauterisation, deep and, above all, immediate; otherwise it is useless or worse. He concludes by saying that the Pasteur method is not absolute. It does not save all hydrophobic patients, just as quinine does not cure all malarias, or salicylate of soda all rheumatisms, or mercury all cases of syphilis; while each of these remedies has a specific action which no one doubts. In like manner the Pasteur method, though not invariably successful, has the incontestable merit of having greatly lowered the mortality from hydrophobia, and may yet be so far perfected as to reduce the victims to the fell malady to an almost inappreciable minimum.

THE LONDON WATER-SUPPLY.

MESSRS. CROOKES, ODLING, and TIDY, on behalf of the directors of the water companies, report that during the month of November of the 175 samples examined all were found to be clear, bright, and efficiently filtered. Throughout November the condition of the water-supply to the metropolis, although, by reason of the continued exceptionally flooded state of the rivers, falling short of the standard usually maintained at this season of the year, showed an appreciable improvement on that prevailing during the latter part of the preceding month. This improvement is greater than would appear from a mere comparison of the mean results afforded by the examination of the two months' respective supplies, the means afforded by the previous month's supply having been kept down by the good results furnished in the early part of the month, before the effect of the floods began to be seriously felt. Dr. Frankland, on behalf of the Local Government Board, says in his report that the water abstracted from the Thames by all the companies, except the Chelsea, was, in respect of organic contamination, of much better quality than that reported upon last month; but the water delivered by the Chelsea Company, which was by far the best in October, was the worst in November, and contained no less than 73 per cent. more organic matter than that supplied by the Lambeth Company on the same day. All these waters were efficiently filtered. The water taken chiefly from the Lea by the New River Company was only slightly better than the best of the Thames waters, whilst that obtained from the same river, but lower down the stream, by the East London Company was inferior to all the Thames waters, except that supplied by the Chelsea Company. Both companies sent out efficiently filtered water. The deep-well waters of the Kent, Colne Valley, and East London Companies, and of the Tottenham Local Board of Health, were, as usual, of excellent quality for dietetic purposes.

THE SICKNESS AMONG THE TROOPS IN BURMAH.

WE gather from a telegram to *The Times* of the 18th inst. that much sickness prevails in Upper Burmah. The Cornwall Regiment at Meiktila have suffered severely from enteric fever. Cholera is stated to have broken out amongst the coolies accompanying the columns in the Chin hills; and glanders is prevalent among the transport mules, much embarrassing the commissariat arrangements. We also gather from the same source that General Sir James Dormer has published a district order since his inspection of the garrison in Burmah, in which he finds fault with the medical arrangements for the care and comfort of the sick in the military hospitals. The *personnel* of the military medical service is wholly insufficient for the wants of Burmah. We are glad to learn that the present unsatisfactory state of affairs is not attributable to any want of energy or devotion on the part of the medical staff, but to the fact that they are short-handed and altogether overworked. It appears the administrative districts in the Burmah command are of enormous extent, and the medical staff is quite inadequate to the requirements. The Indian Government, it is alleged, cannot plead ignorance of the facts, for they have been repeatedly, but vainly, brought to notice; and the Government recently refused to add another administrative medical officer to one of the districts. Assuming the facts to be as stated, of which we fear there is little doubt, they speak for themselves, and require no comment.

EFFECTS OF SULPHONAL.

IN the *Journal of Mental Science* for the current month Dr. Carlyle Johnstone records his observations on the effects of sulphonal on fifty patients suffering from various kinds of mental disorder, including general paralysis, melancholia, and mania. His experiences with the drug point to the conclusion that in properly regulated doses it is an efficient hypnotic, and, compared with that of other hypnotics, its action is fairly certain and constant. The sleep produced by it is natural and undisturbed by dreams; it has no injurious effect on the appetite, circulation, respiration, or temperature, and the general health does not suffer under its use. After a time the dose may be reduced, or it may even be discontinued, and the patient still continue to sleep well. Dr. Johnstone also found that it had a distinct sedative action in mental excitement and distress, and could be employed with great benefit in cases of insanity, especially such as are of recent or acute character. Its complete tastelessness also is a recommendation in such cases, allowing its combination with food or in milk in such a way as to escape the notice of the patient. The chief drawbacks were found to be its slowness of action, and often the persistence of its soporific effect during the succeeding day, together with at times confusion, giddiness, and fatigue. After repeated doses a dreamy confusion was noticeable, and subsequently slight weariness and fatigue, followed in a few cases by enfeeblement and shakiness of

Digitized by Google

locomotion; but nothing occurred which could be called an alarming symptom. As a rule, indeed, the mental condition improved, the excitement, irritability, and motor restlessness being diminished and the wretchedness dispelled. It will thus be seen that the writer's conclusions are in accord with the majority of those already published, and that, while regarding sulphonal as by no means a perfect hypnotic, he is inclined to give it a very important place in the treatment of sleeplessness and restlessness generally. The best doses he found to be between thirty and forty grains, and it should be given just before the patient lies down. The freedom of the drug from taste and smell, as has been said, is one of its advantages, and renders its administration easy.

THE PREVENTION OF RABIES.

WERE it not that experience has fully proved, both in England and on the Continent, the efficiency of the muzzle as a preventive of the spread of hydrophobia, we might excuse the delusion that the disease lately so prevalent in this country has died a natural death. The facts mentioned in THE LANCET of April 5th, 1890, however, show too close a connexion between the prophylactic method and its effect to admit of any real doubt upon the subject. The past year has been a period of probation. The immunity conferred by the muzzling order has not, perhaps, unnaturally been taken as justifying its discontinuance in favour of the less irksome system of collar registration, and so far, there is every reason to believe, with fairly satisfactory results. In this way such cases of rabies at least as arise among stray dogs, and they comprise the greater number, should, if the regulations are stringently enforced, be held in check. Of the efficiency of the muzzling system and the justice of its application two years ago we cannot entertain a doubt. In its absence registration is and must remain for some time to come quite indispensable. It is difficult indeed to see how, without some such preventive arrangement, security against the disease can be relied upon. We trust, moreover, that, on the least sign of a recrudescence of the disease, in the interest of our faithful friends the dogs as well as of the human race, muzzling may again be strictly enforced.

DEATH FROM ATTENDING FUNERALS.

IT is one of the privileges of members of the medical profession that they have the opportunities of seeing the various abuses incidental to our everyday life, and of suggesting the remedies, which, however, are not generally heeded. By the death of the Duke of Clarence and Avondale the public mind has been thoroughly aroused to the danger which has for years past been repeatedly pointed out in these pages. All the various suggestions now made as to keeping the head covered and shortening the service at the graveside, so far from being original, as the various correspondents would appear to imply, were suggested in THE LANCET years ago. Our local correspondent forwarded to us details of the death of a leading Liverpool citizen whose death was the direct result of a chill caught while standing bareheaded at a funeral, and at his own funeral, which followed but a fortnight after, the attendant relatives and friends were requested to remain covered. Now that attention is strongly drawn to this painfully important matter it may be profitable to supplement the preceding with some further remarks. None should attend funerals in such weather as now prevails except those who are in robust health; the aged and those whose health is in any degree delicate should be absolutely forbidden to do so. It is not only at the graveside that fatal chills are acquired. Cemetery chapels are proverbially chilly places, and it is to be feared that care is not taken to sufficiently warm them previously. This is all the more imperative, since in cold and inclement weather the whole of the service (except what must necessarily be said at the grave), and particularly any address or panegyric on the deceased, should be said in the chapel. Some clergymen who wish strictly to obey the rubrics may object to saying in the chapel what is ordered to be said at the graveside. We would point out, however, that there is one rubric which it is necessary to disregard—viz., the dipping of an infant into the water at baptism. In spite of the plainest words which a rubric can have no child is dipped however "discreetly and warily," and the attendants are not even asked whether the child "may well endure it." Whether the rubric was ever obeyed is a question which has never been satisfactorily answered; it is enough that no infant should be subjected to such a risk. By a parity of reasoning it may be urged that the attendants at funerals ought not to be exposed to a similar danger.

CARDIFF AND IMPORTED INFECTION.

A PROPOSAL is before the Cardiff corporation, in their capacity as port sanitary authority, to place on a more permanent and efficient footing the sanitary inspection of vessels entering the port, the more especially with a view to prevent the importation of infection. To fulfil the various requirements which are held to be necessary by Dr. Walford, the port medical officer of health, it would be requisite to employ a steamer, which should be constantly at the disposal of the port sanitary staff, and to add one or more inspectors to the staff. Cardiff has more than once been thus compelled temporarily to widen the scope of port inspection, and has doubtless found the hire of a steamer costly; but, if such an arrangement as is now proposed were adopted as a permanent measure, the port would be much more secure as regards imported infection, always a source of expense and of possible panic, and hindrances to commerce would, to the utmost, be prevented. Other ports, such as the Tyne port, have long since adopted a similar system, and it can hardly be otherwise than an advantage at Cardiff, where the circumstances of the port in relation to the Bristol Channel tend to present somewhat exceptional difficulties under the system now in operation.

PROFESSOR GAIRDNER ON CLINICAL INSTRUCTION.

PROFESSOR GAIRDNER, whose interest in clinical medicine, and especially in clinical teaching, is unsleeping, has been reading Sir Andrew Clark's lecture and our leading article on the subject, and kindly forwards us a lecture, introductory to a course of clinical medicine, which has never been published, but which is a type of one he is in the habit of giving to his students in printed form. It treats of the real import and method of clinical instruction, and, we need not say, goes thoroughly to the root of the matter, insisting that both instructor and instructed are to be in the presence of the patient, and learning the lessons of disease together from the absolute source of all real and final knowledge in respect to disease—*the sick man*. The lessons of a practitioner to his apprentices in the days when apprenticeship still existed were true clinical instruction; and with such a man as Abercrombie, who practised this method exclusively, they must have afforded clinical instruction of the best and highest kind. Dr. Gairdner adds that a well-conducted dispensary, in which the physicians not only see the patients at the dispensary, but follow them up at their own homes and along with their pupils, is also a very fruitful and admirable field for true clinical instruction, and one which only requires competent and devoted men to make it at least equal, if not superior, to any other. Strange to say, however, neither of these is

Digitized by Google

counted as formal clinical instruction in the curriculum of study. Dr. Gairdner affirms such kind of instruction to be desirable, and regards it as a modification of the German *Poliklinik*, or clinique of the town. With his usual precision, he indicates the only limitations to the usefulness of this mode of instruction. The one is the limited number of men fit for such work, and the other is the risk of "hurry-scurrying" through thirty or forty cases in an hour, as sometimes must occur in the out-practice of hospitals. It is one of the recommendations of more private lessons, as in dispensary or general practice, that, being given in the very homes and houses of the patients, there is the more guarantee for that humane and considerate treatment of the patient and for a certain amount of thoroughness on which both Sir Andrew Clark and Professor Gairdner so properly insist. There are surely among the many thousand practitioners of Great Britain not a few who could give most valuable lessons in the art of detecting and treating disease. The remainder of Dr. Gairdner's lecture deals with the importance of right methods of clinical instruction, the place of clinical lectures, the physician and the patient and the ethics of a clinical course, the details of clinical work, the verification of details, and the composition of clinical lectures proper. He thinks that a hospital patient, as compared with a rich man, derives immense benefit from the methodical investigation of his case. He allows that "lecturing" is often overdone in clinical teaching, and he insists, as all good teachers do, on treating the student and even his mistakes with respect. It is clear that the methods of clinical instruction are about to receive more attention than ever, and they both deserve and need such attention.

BURIAL REFORM AND THE CITY CHURCHES.

AT a recent meeting of the Church of England Burial Reform Association, held in the vestry of St. Edmund the King, Lombard-street, under the presidency of Archdeacon Sinclair, allusion was naturally made to the recent disclosures at the neighbouring church of St. Mary, Woolnoth. The Rev. F. Lawrence, the indefatigable secretary of the Association, observed that all the officials of the last-named church had suffered from sore-throats in consequence of the foul air in the church arising from the large number of dead bodies in the vaults beneath. He quoted the words of Sir John Simon, to the effect that the most successful hermetical sealing of dead bodies might retard, but could not possibly prevent, the escape of poisonous gases which mingled with the air in the church above, to the great detriment of those assembled there. The experience at St. Mary's only added another example to the several other City churches which had been rendered equally unwholesome. The bodies entombed beneath that church will have to be removed and buried in some suburban cemetery, as is generally done now, and as should have been done always.

PERITONITIS FROM PERFORATION OF THE INTESTINE IN UTERO.

DR. ANTON GENERSICH of Clausenburg recently exhibited at a meeting of a Hungarian Pathological Society a case of peritonitis occurring in an infant which had doubtless originated from perforation of the small intestine before birth. He referred to Dr. Zillner's report of several somewhat similar cases where the sigmoid flexure had been ruptured, the explanation proposed by Dr. Zillner being that the rupture was due to distension by meconium of a coil of intestine fixed between the vertebral column and the abdominal walls. He considered that pressure and distension of this kind must occur even in normal parturition; but this view is combated by Dr. Plataut, who insists that the rupture is due to fæcal accumulation without any external mechanical cause, such as the pressure exerted in labour. In Dr. Genersich's case an abscess containing meconium had formed under the umbilicus, this abscess communicating with the ileum by means of an infundibuliform passage. The extent and character of the granulations, which had become calcareous in some places, and the firm adhesions in the neighbourhood of the lesion, showed that the perforation must have taken place some time before birth, as the child only lived forty-five hours. It is probable that the pressure during birth and the entrance subsequently of pathogenic bacilli through the alimentary canal caused a sudden increase of the peritonitis as well as the phlegmonous inflammation of the abdominal walls. The spontaneous perforation of the ileum is, as has been well pointed out in this country in somewhat similar cases by Mr. Bland Sutton, intelligible only by referring to the embryology of the intestines. A small Meckel's diverticulum may have been split on the spontaneous reduction of the normal umbilical hernia, or the obliteration of the physiological umbilicus may have remained incomplete, so that on the retrogression of the umbilical coil of intestine a small aperture was left, from which the meconium percolated into the peritoneal cavity, subsequently becoming encapsulated by adhesions between the intestines, the omentum, and the abdominal walls. The latter view is the one which Dr. Genersich considers the most applicable in the present case, as a most minute examination resulted in finding no vestige of a diverticulum, while the large intestines were found to be rather thin.

IS CHELMSFORD WATER-LOGGED?

AN increase of diphtheria in the town of Chelmsford, taken together with the now admitted circumstance that the diffusion and maintenance of that disease are in some way related to damp and cold soils, has raised the question as to whether this Essex town is water-logged or not. This is a matter which ought long ago to have been set at rest, for it is no less than twenty-six years since Dr. Buchanan presented to the Privy Council Office his classical report on the relation of phthisis to subsoil wetness, and in this he quoted the case of Chelmsford as one of the crucial proofs of his contention. He then showed that in a number of towns where deep sewerage had lowered the subsoil water there had been a remarkable diminution in the rate of phthisis mortality; but when he came to Chelmsford, where works of equal importance had been carried out, no vestige of any corresponding diminution of the phthisis death-rate could be discovered. The explanation, he maintained, lay in the fact that mill-rights, with their corresponding flood-gates below the town, held up the river water, and so prevented any reduction of subsoil wetness beneath the town. If ever there was a case for immediately securing the benefits elsewhere obtained by the result of deep drainage it was at Chelmsford, and many have doubtless come to the conclusion that the story of 1866 is a matter of curious past sanitary history. Such observers will be astonished to find that a discussion has recently taken place in the Town Council on the subject, "Is the town water-logged?" and that the question still arises in 1892 whether the heading-back of the river water at such places as Moulsham Mill shall be prevented by purchasing the mill rights. The most that could be said at the meeting was that the whole of the soil beneath the town was not water-logged, the South Ward standing upon a comparatively dry surface. But, as regards the remainder of the town, it would seem that matters stand just where they have done all these twenty-six years in which Chelmsford has served as witness to the injurious effects of a maintained high level of subsoil water. Now that the matter is again

Digitized by Google

to the fore it is to be hoped that there will be no hesitation in dealing with it; and in the meantime it would be interesting if those who are fully acquainted with the actual facts affecting the South Ward from a hydro geological point of view, and who have access to the vital statistics, were to work out the incidence of the phthisis mortality between 1866 and 1892 on the South Ward and the remainder of the town on the same lines as Dr. Buchanan did in his original report.

POVERTY OF HOSPITALS.

THE *City Press* draws a doleful picture of the shrinking subscriptions to the metropolitan hospitals, and prophesies that, unless both the existing deficit be wiped off and the annual subscriptions increased, these noble and voluntary institutions will soon become State hospitals supported by public rates. It takes a gloomy view of the change of spirit and administration which will follow this radical change of support. There is, no doubt, too much reason in the fears of our contemporary, and we earnestly trust that its comments may be so studied by the rich men of the City that this dire misfortune may be averted, and that the voluntarily supported hospitals may continue to be among the "glories of England." It will contribute to this end if all promoters of new hospitals be discouraged, and the charity of the metropolis concentrated on the maintenance of the existing ones.

CREMATION, BURIAL, AND EXHUMATIONS.

IN THE LANCET of Jan. 2nd, page 42, in an annotation on burial reform and its legal regulations, it was observed that "no other method can ever so fully satisfy the possible needs of a criminal investigation as that which allows the exhumation of the body." While fully maintaining the soundness of this position, it is at the same time most important that this should not be made any excuse for haste, carelessness, or an undue desire to oblige in the giving of a certificate of death on the part of medical practitioners, in registering a death on the part of registrars, or in burying without a burial order on the part of cemetery or churchyard officials. For although the body may remain in the ground and be available for exhumation, post-mortem examination, and chemical analysis, all these may be in vain, and a medical certificate given with an imperfect knowledge of all the circumstances surrounding the last illness, followed by a hasty burial, may defeat justice as completely as if the body had been cremated. This must be rendered more probable if burial reform grows in favour as it is hoped it will. For although much valuable information may be obtained by an examination of bodies even in an advanced state of decomposition, and though toxicological science may detect poison after months and even years of burial, still pathological and chemical research both have their limits, and some poisons could be named which would defy detection even within a short period after death. In every or any case of death from poison or other unfair means, it is much better to detect this before rather than after the body has been committed to the grave. The two following cases will prove the truth of the preceding remarks. For obvious reasons the names of persons and localities are suppressed. Some years ago a man went to his work in his usual health at his usual hour one morning. He returned to his dinner, after eating which he was seized with convulsions and died. A surgeon examined the body and gave a certificate, and the body was buried. Some weeks after suspicious circumstances came to the knowledge of another surgeon, who succeeded in causing the exhumation of the body, its examination, and the despatch of the viscera to an eminent analytical chemist. Strychnine was indicated by the symptoms as the poison which had caused death, but it could not be detected even by the most refined processes adopted by the analyst first employed, nor by a second one to whom the viscera were also sent. The bodies of two children whose deaths occurred previously were also exhumed, but the chemical inspection of the viscera was also negative. A person was put upon trial for murder, but although the case was a most suspicious one, the non-detection of poison was fatal to a conviction, and the prisoner was acquitted. In the second case a child died under circumstances which aroused the suspicions of one of the two medical attendants, who were respectively a retiring and a remaining partner. The former was dissatisfied with the mother's manner and puzzled with the symptoms, which were not those of any natural form of disease incidental to childhood. A second child died very soon after, and a certificate was given and the body buried. Later on the husband and father was taken seriously ill with similar symptoms, but fortunately was saved by copious vomiting and violent walking exercise. Lastly, the wife and mother was also suddenly seized with similar symptoms and arrested on a charge of attempted suicide. Then followed a full inquiry, with exhumation of the two bodies and the detection of morphia. The prosecution had to contend with the difficulties which will always arise where a charge of murder is preferred some time after the death of the victim and when the circumstances are not fresh in the memories of the various witnesses, and the woman was acquitted. Still greater is the difficulty when a medical witness has to avow having given a certificate of the cause of death which was palpably incorrect, when those who make the necropsy have to deal with a decomposed corpse, and when the analyst endeavours to detect a vegetable alkaloid under circumstances very unfavourable to its discovery.

MATERNAL IMPRESSIONS AND DEFORMITIES IN CHILDREN.

THIS always interesting subject is again discussed in an article in the *Glasgow Medical Journal* by Dr. Halket. He first of all enumerates the cases of congenital deformity which had occurred in his own practice, and then some of these are discussed with reference to their connexion with experiences of the mother during her pregnancy. While fully recognising the great difficulty there is in reasonably regarding deformities as definitely connected with maternal impressions, Dr. Halket is strongly impressed with the cases which have been put on record by men of undoubted standing and unimpeachable veracity in which such a connexion seemed extremely probable, and his own experience has strengthened the impression that the connexion between certain deformities and mental states which the pregnant mother has experienced is occasionally at least something more than a mere coincidence. In one of his cases the child was a boy, the second child of his mother, and the first child was healthy and well-formed. The child under consideration had his nose only partially developed, there being only one nostril. The right eye was situated much further back and at a lower level than the left eye, and the child was unable to close it. On the right side of the forehead there was a small growth half an inch long, tipped with bone, which looked like a small horn. The child was otherwise strong and healthy, and lived till it was fifteen months old, when it died of acute bronchitis. This child's mother was the wife of a drunken husband, who was not unaccustomed to kicking and otherwise maltreating her, and to the mechanical effect of this violence, and not so much to mental effects, Dr. Halket is inclined to attribute this deformity. But perhaps the most interesting case of all is one in which the child was born alive without the index and middle fingers of one of its hands. The mother was a young woman, who knew nothing about maternal impressions, and as soon as she knew of the deformity she

Digitized by Google

volunteered the information that she had to work for some months after her marriage, and that the foreman under whom she worked had lost two fingers through an accident, and that when she saw his hand for the first time she had a "grueing" or shivering, and that every time she saw him she could not keep from thinking of his deformed hand. The other cases which Dr. Halket relates are for the most part deformities which he ascribes not so much apparently to some actual isolated impression made on the mother as to habits of intemperance, to prolonged grief, or to anxiety which would in all probability have a very bad effect on the child in utero as well as upon the mother, but why a certain deformity should result, such as cleft palate or harelip, seems to be rather difficult of explanation. The subject is an obscure one, though interesting. If these deformities following mental impressions are only coincidences, they are very striking in some cases; and if, on the other hand, there is any causal connexion between the impression and the deformity, it is very difficult, if not impossible in the present state of our knowledge, to explain its *rationale*.

THE CLAIMS OF SANITARY SCIENCE UPON THE CLERGY.

IN the physical world we look in vain for sudden transitions in structural arrangement. Changes and differences abound, indeed, but all is relative and gradual. So likewise it will doubtless be found that the more we learn of its spiritual counterpart the clearer will be our evidence that there too the same rule holds good. Facts which on their occurrence may appear singular, and even startling, will exhibit relationships with others previously known, though not till then in all their bearings. It were strange, therefore, if men and their works, essentially natural as they are, did not illustrate the same principle of mutual relation and interchange. We are constantly learning that they do so, and however we may map out our life-work by social limitations, as doubtless we must for the sake of mere efficiency, there will always be borderlands where its provinces merge within each other and claim a common interest. The scope of such a borderland is sketched with simplicity, clearness, and moderation by the Rev. C. G. K. Gillespie, in a brief paper which discusses the Claims of Sanitary Science upon the Clergy. The author's intention is to show that the principles of elementary sanitation lie almost as much within the sphere of clerical duty as of medicine or sanitation. Matters of household hygiene may thus be regarded as common property, and a due appreciation of their importance would doubtless go far to maintain the just influence of parish clergy. In advocating the addition of a course of instruction in the outlines of sanitary science to the plan of clerical study the author (who is himself a certified inspector) is conscious of some interest in a field inseparable from that of morals, while duly conserving the stronger claims of medical neighbours.

ACROMEGALY.

M. GABRIEL GAUTHIER records the details of the post-mortem examination of a case of acromegaly in the current number of *Le Progrès Médical*, the clinical facts of the case having been published in the same journal two years ago. The patient died, "like most acromegalics," from marasmus and syncope, and during the last month of his life he had some attacks of pseudo-erysipelas on the forehead, nose, and cheeks. The post-mortem examination showed thickening of the cranium at the occipital protuberance, but not elsewhere. The vessels of the pia mater were voluminous and engorged, and in removing the brain from the cranial cavity it was found that the pituitary body was replaced by a tumour the size of two thumbs, filling the sella turcica and overlapping it. The tumour was nearly spherical, and was enclosed in a special envelope of dura mater, tense and thinned. On incising this, some pulpy material escaped, the whole mass weighing thirteen grammes. Microscopically, no other elements than those of cerebral tissue could be found in it. The optic and ocular nerves in contact with the tumour were unaltered, the circular and cavernous sinuses were especially compressed, whilst the coronary sinus was hardly to be seen. The pituitary fossa was considerably enlarged and the clinoid processes partly destroyed, whilst the shell of bone over the sphenoidal sinuses was very thin. There was no lesion of the brain itself, or of its nerves, or of the sympathetic. The thyroid body was normal. As to the viscera, there was some degeneration of the myocardium, and the valves of the heart were normal, but the orifices large; the kidneys were large and soft; the liver, spleen, and lungs normal. It was impossible to examine the whole skeleton, but the observation of the condition of the fingers noted during life was verified by dissection, the phalangeal joints of the left ring finger showing marked changes, such as wasting of the articular ends of the phalanges and ankylosis of the terminal and middle phalanges.

DRUNKENNESS AND CRIME.

THE *Daily News* of the 18th inst. gives the chief details of the new Government Bill for the suppression of drunkenness in Germany, of which we have already given some particulars. Amongst other provisions, publicans will not be allowed to turn drunken persons out of their houses without providing for their safe conduct home, the expenses to be paid by the drinkers. The Bill provides for the appointment of guardians to habitual drunkards. The measure is likely to be much opposed. But it is a Government Bill, and the Emperor's interest in it will count for much in the attention it will receive. Sir Lyon Playfair has induced Sir Henry James to try to define the bearing of the element of drunkenness in criminality. Even Sir Henry James has found it difficult to do so. The following is a summary of his conclusions:—

"In determining the legal character of the offence committed, drunkenness may be taken into account—1. Where it has established a condition of positive and well-defined insanity. 2. If it produces a sudden outbreak of passion occasioning the commission of crime under circumstances which, in the case of a sober person, would reduce the offence of murder to manslaughter. 3. In the case of minor assaults and acts of violence it never can form any legal answer to the charge preferred, but it may either aggravate or mitigate the character of the act committed—probably the former. 4. As to the effect that should be given to drunkenness when determining the amount of punishment to be inflicted, no general rule can be laid down. Its existence may be considered, and may tend either in the direction of increasing or diminishing the punishment imposed. This is all the help I can give you. I am afraid I have done but little to solve the problem you have placed before me."

One thing seems clear in the tendency of civilisation, that drunkenness itself should be made more definitely an offence than we have been accustomed to regard it.

PLASTIC BRONCHITIS.

DR JÓZEFOWICZ describes in the *Gazeta Lekarska* an interesting case of that somewhat rare disease, plastic bronchitis, occurring during the course of acute articular rheumatism. The patient was a student, nineteen years of age, who complained of a troublesome cough with lancinating pains in the chest. The expectoration was muco-purulent, and contained some blood and fibrin. In the course of the disease one night a sudden paroxysm of cough occurred, with copious bleeding from mouth and nose, and expectoration

Digitized by Google

of flesh-like masses. Dr. Józefowicz, on examining the expectoration, found in it masses of coagulated fibrin, partly presenting ramifications, as if coming from the smallest bronchi, and partly cylindrical, corresponding with the shape of the larger bronchi. Shreds of membrane of various thickness were also found, probably coming from the largest bronchi, or possibly from the larynx and nose. The microscope also discovered numerous pus-corpuscles, epithelial cells, and red blood-corpuscles. The etiology of plastic bronchitis is not sufficiently known. Phthisis, bronchial catarrh, general debility, atmospheric influences, diphtheria, and typhoid fever are mentioned as causes of the disease, and it is also found associated with mitral insufficiency or stenosis of the auriculo-ventricular orifice. This connexion existed in the present case, as, even during an early period of the rheumatic affection, both these heart symptoms were diagnosed. Another symptom to be taken into serious account was the infiltration of the lung parenchyma, which could not be referred to an existing fibrinous pneumonia. Probably it was due to an exudation of blood, or possibly of fibrin, into the pulmonary vesicles. Hæmoptysis is generally insignificant and very rarely profuse.

THE EPIDEMIC AND THE DEMAND FOR NURSES.

IT is inevitable that one of the natural consequences arising out of a widespread and serious epidemic should be the extraordinary demand which it creates for the services of all whose part it is to attend upon the sick. Our readers are familiar with the numerous proofs of such a dearth afforded by experience of the present visitation of influenza, especially as regards the provision of trained nurses. The valuable assistance rendered to the sick by these latter was never probably so fully recognised as now, nor its absence in urgent need so deeply felt. Happily, however, we are not quite without resource in the circumstances. We cannot, indeed, fall back upon any reserve establishment. It were well if we could, and the lesson of prudence in this matter taught by the present nursing difficulties will *not*, we hope, be forgotten. Meanwhile there is much to be said for the proposal to create a temporary central bureau which would arrange with friends of the sick for the ready transfer of nurses wherever available. We must also look to medical men for some help in the present emergency. The needs of all sufferers are not equally great. The care of some who may prefer a trained nurse, though not seriously ill, may very fairly be entrusted to judicious relatives. Others will find the attendance of careful and sensible persons acting under the guidance of practitioners, though not specially skilled, quite equal to all their needs. In either case the nursing capacity of men and women more perfectly trained for service in the sick room would be freed for duties of greater responsibility. It is for the practitioner to use his influence with due discrimination in seeking to secure this result. We should remember, too, that such irregular aid as we have mentioned is often very far from inefficient. It was upon this that our progenitors relied, and not in vain, since qualities like obedience, kindness, and good sense prove of great value in nursing, even without technical instruction. Supervision on the part of the medical man in charge will make up for some deficiency in the latter desideratum.

BACK-TO-BACK HOUSES.

THE question of back-to-back houses continues to be one of discussion in several of our northern towns where this method of house construction has been carried out. From a few persons it receives support. Dr. J. H. Bell of Bradford has, in a communication to the Yorkshire branch of the Society of Medical Officers of Health, brought forward certain statistics to show that by comparison of certain areas in that borough the general rate of mortality was small in continuous rows of back-to-back houses, and distinctly higher in "through houses." What the explanation of this circumstance in the three localities chosen was we do not profess to know; but we are quite certain that the absence of means of through ventilation in the one set of dwellings and the facilities afforded for through ventilation in the other did not cause the difference referred to. And it is equally certain that no one of any intelligence has assumed that the rate of mortality in dwellings is governed by this one consideration of through ventilation only. The age and character of the population inhabiting such areas may have a most important effect in determining the amount of death; the question of soil and wholesomeness generally of sites and buildings may also have some effect; but one thing is sure—namely, that given dwellings and a population in every respect alike, except as regards the question of the through ventilation of the houses, those dwellings which have such means of ventilation will unquestionably be found more healthy than those lacking it. A very different view of the subject to that suggested by Dr. Bell was taken by his audience, both at the recent gathering at Hull and at the Leeds conference in October last. Indeed, at the latter it was decided to express to the Local Government Board the decision of the Society, to the effect that back-to-back houses, which do not admit of through ventilation from opposite sides, are essentially insanitary, and have been proved by experience to be prejudicial to the health of their occupants; that every effort should be made to convert them into "through houses"; and that their erection in the future should be prohibited. They further petitioned the Board to obtain an Act of Parliament embodying this prohibition, fixing a minimum width of front and back streets, and requiring for every new house a separate back yard and closet. The latter is a provision of the utmost importance; indeed, the absence of decency and privacy in connexion with the closet accommodation of back-to-back houses is one of the gravest defects attaching to that highly objectionable method of house construction.

FOREIGN UNIVERSITY INTELLIGENCE.

Bologna.—Dr. Maiocchi of Parma has been appointed to the chair of Dermatology and Syphilography.

Heidelberg.—Dr. Knauff has been promoted to the Professorship of Forensic Medicine and Hygiene.

Kiel.—Drs. Kosegarten and von Starck have been recognised as *privat-docenten* of Otology and Medicine respectively.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. E. Lipp, Professor of Dermatology in the University of Gratz.—Dr. L. de la Pascua, formerly Professor of Hygiene in Mexico.

THE Belgian Society of Gynæcology and Obstetrics is about to institute an International Congress for the discussion of questions cognate to the above subjects. The first meeting will be held at Brussels in September next, from the 14th to the 19th, and will concern itself with the following topics: Pelvic suppuration, extra-uterine fœtation, and placenta prævia. The meetings will be held every fourth year, and will take place alternately in Switzerland and Belgium. Communications to be addressed to the general secretary, Dr. Jacobs, 12, Rue des Petits-Carmes, Brussels.

MR. A. H. WILSON, L.R.C.P.Lond., has been selected as chief medical officer to the General Post Office, vice Mr. G. C. Steet, F.R.C.S., retired.

Digitized by Google

WE regret to record the death of Surgeon-General G. M. Slaughter at Alderen Manor, Sandhurst, on the 9th inst. The late surgeon-general was the principal medical officer at Portsmouth at the time of his comparatively recent retirement from the service, and was sixty years of age at the time of his death. He joined the army in December, 1865, and passed through the several ranks of the department, being promoted to that of surgeon-general in January, 1890. He served with the 7th Hussars in the Indian campaign from February, 1858, to March, 1859, and was present at all the principal engagements, including the siege and capture of Lucknow. The late surgeon-general was a very industrious and conscientious officer, and an able and popular administrator, and his death so soon after his retirement will be much regretted by the officers of the medical staff.

A CORRESPONDENT draws our attention to the monthly official Portsmouth and Southern District Directory for the month of January, edited by the Deputy Assistant Adjutant-General, in which he considers a somewhat invidious distinction is made in the use of the compound titles of the Army Medical Staff and those of the veterinary surgeons. The medical officers are described by the compound titles, whilst under the heading "Army Veterinary Department" is the following entry: "Veterinary Officer—Major——" The distinction thus made has been construed in some quarters as an instance in which the military element is intentionally denied to the medical staff in contrast to the Veterinary Department. May not the printer be responsible for the discrepancy?

AT the Medical Society of London, on Monday last, before the commencement of the second Lettsomian lecture, the President alluded in feeling terms to the death of the Duke of Clarence and Avondale. Sir Joseph Fayrer proposed that a vote of condolence and sympathy should be forwarded to the Prince and Princess of Wales, and this was seconded by Professor Wm. Rose, and carried *nem. con.* This vote of the oldest medical society is a fitting expression by the members of the profession of a feeling that we are sure is shared by every practitioner of medicine, and to which we ventured to anticipate at the earliest possible opportunity in our leading article of last week.

IN a paragraph in THE LANCET of last week (page 159) we stated that Sir Andrew Clark will resume his instructions in Clinical Medicine at the London Hospital on Jan. 19th at 2 o'clock. We understand that this announcement was not quite correct. The instructions will be given on Tuesdays at 3 P.M., commencing with Tuesday next, the 26th inst.

THERE will be a debate on Phagocytosis at the Pathological Society of London on February 16th. Members and others wishing to take part in it are requested to give notice to Dr. Charlewood Turner, the medical secretary.

YELLOW FEVER IN BRAZILIAN PORTS.—The Cunard mail steamer *Bothnia*, which arrived at Queenstown on the 19th inst. from New York, brings intelligence of the arrival at that port of the Liverpool steamers *Plato* and *Ptolemy* from Rio Janeiro, *viâ* St. Lucia. While at the former port several of the crews of both vessels were stricken with yellow fever, and while on the passage to New York the chief steward of the *Ptolemy* and a fireman of the *Plato* died of yellow fever and were buried at sea.

THE RUSSIAN FAMINE.

ANALYSIS OF THE BREAD IN USE.

AN unparalleled disaster has befallen a great people. A famine is laying waste fifteen to eighteen provinces of the Russian empire. Each of these provinces is as large as England, though, fortunately, not so densely populated. This disaster cannot be compared even with the Irish famine of 1846, for the present Russian famine affects a much larger population and its consequences will be more far-reaching. Indeed, this famine is a stupendous event. It is impossible to exaggerate its importance, whether we look upon it only from our own restricted point of view—namely, as affecting the public health,—or whether it be considered in its political and economical bearings. Official statistics give us some idea of the magnitude of the disaster; and it is most essential, in dealing with this question, to thoroughly understand that this is no mere local trouble, but that whole nations, as it were, are being struck down; for a Russian province is large enough to make a nation in itself. According to these statistics, we find that the wheat sown in autumn gave, in sixty Russian provinces, from the years 1883 to 1887, an average yield of 26,000,000 hectolitres. The present year the yield has been equal to 25,000,000 hectolitres; but when we come to the wheat sown in the spring we find that instead of an average harvest of 63,000,000 hectolitres there were only 38,000,000 hectolitres gathered. So far as the food of the great mass of the people is concerned, the rye crop is of much more importance. The average yield of rye for the sixty provinces is 249,000,000 hectolitres; this year only 190,000,000 hectolitres were gathered in. For oats there were 169,000,000, instead of 195,000,000, hectolitres. The aggregate of all crops was 517,000,000 hectolitres, instead of 645,000,000, thus showing a deficit of 128,000,000 hectolitres.

To the Western European this may not seem an insurmountable disaster. In France the harvest of 1879 yielded only 209,000,000 hectolitres, instead of 260,000 000. Roughly speaking, the proportion in both cases is the same—there was a falling off in the harvest of one-fifth; yet there was no famine whatsoever in France, while in Russia thousands are now dying for want of food. But in France there was money enough to import from abroad sufficient corn to make up the deficiency, and there were railways and roads by which this imported corn could be conveyed to the districts where it was wanted. Then, again, if the deficit were spread all over Russia the evil would not be so great; but it is concentrated, and, out of a population of about 100,000,000, affects some 27,000,000. The average production of corn of the famine-stricken districts is equal to 240,000,000 hectolitres, or 37 per cent. of the whole Russian harvests. The harvest in 1891 was of 141,000,000 hectolitres, or 45 per cent., less than the average harvest. Then if we consider individual provinces the disaster becomes still more apparent. Thus in Voronej the harvest amounted to 28,000 000 hectolitres in 1888; to 13,000,000 hectolitres in 1889, to 31,000,000 in 1890, and to less than 4 000,000 in 1891. To import from abroad the 128,000,000 hectolitres of grain would cost, it is said, £60,000,000, and require about 6400 ships. The people of France actually spent about this sum from 1879 to 1880 so as to purchase the 86,000,000 hectolitres of wheat and flour which they needed to make up for their bad harvests; but then in France there are 64 kilometres of railway lines to every 1000 kilometres square of land, while in Russia there are but 5 kilometres of railway to the same amount of land. Thus it is extremely difficult—in some cases absolutely impossible—to convey relief to the distressed districts. Also this relief must be given—it cannot be sold; for there is a money famine as well as a rye famine. Since 1879 Russia has exported annually some 100,000,000 hectolitres of grain, for which it has received about 300,000,000 roubles. But exports have been prohibited, and this, though done somewhat late in the day, will reduce the flow of foreign money into Russia to the extent of some 200,000,000 roubles.

As in Russia private initiative is not tolerated, and societies formed for the purpose of relieving the victims of

Digitized by Google

the famine are declared to be illegal, we can only look to the Government to cope with the famine. But the Government so far has not devoted to this purpose as many paper roubles as there are pounds sterling required. Indeed, the Government itself is in sore difficulties. As one instance, we may mention that in 1890 some 4,000,000 hectolitres of grain were used for distilling purposes, and the tax on the alcohol thus made amounted to 270,000,000 roubles. But this prolific source of income is now checked. It is difficult to obtain the grain to distil, and the prevailing poverty naturally reduces the consumption of alcohol. Such briefly and in broad lines are the main features of the present famine.

Perhaps, in this long story of woe, what has most shocked the English public is the account of the cruel, heartless frauds practised by those who have adulterated the flour bought for the relief of the famine. Anything seems good enough for a Russian peasant to eat; and not only is adulteration practised in a wholesale, but also in a most unintelligible, manner. We have had sent to us a specimen of bread from the famine district of Nijni-Novgorod. According to our information this sample is a good illustration of the extraordinary submissiveness and the contented disposition of the Russian moudjic. Hearing that there were friends in England who wanted to see some of their bread, these people made it a matter of pride to send as good a specimen as possible. Perhaps they thought their English friends meant to eat it, but any other person excepting a Russian would, under the circumstances, have sent the worst and not the best sample. Also it should be noted that this bread was made at the end of the month of November, and by this time the distress must be much more acute. Consequently it can only be looked upon as exceptionally good, rather than particularly bad bread; yet many persons to whom we showed the sample failed to recognise that it was bread at all. It is dirty-brown in colour, and looks like coarse peat. It was evidently rye bread, and as such could not be otherwise than dark in colour. On fracture a slightly earthy and sour smell was observed, but with the features which characterise rye meal. Coarse particles of husk, leaves, and small seeds could be seen with an ordinary lens. An analysis of the bread gave the following results expressed in parts per cent.

ANALYSIS OF RUSSIAN BREAD.

		Per cent.
Moisture		22·22
Organic matters—		
Starch	35·33	
Sugar, gum, &c.	10·01	
Nitrogenous substances	14·81	
Woody fibre	10·40	
Fat	1·60	
		72·15

Mineral matters—		
Phosphates of potassium, magnesium, and lime		1·42
		100·00

These analyses show that the main differences existing between the Russian sample and the samples of rye flour and good rye bread in the kind and amount of its constituents are as follows:—

Starch.—The amount of this carbo-hydrate in the Russian bread is evidently very low—in truth, nearly 30 per cent. less than that contained in good rye or wheaten bread. Considering the fact that the carbo-hydrates, including starch, contribute largely by their capacity for rapid metabolism to the production of heat and mechanical work, and also that their use greatly favours an increase in the body, and especially of albumen and fat, the food value of the bread in this respect is seriously affected and materially reduced.

Now turning to the *Sugars, Gum, &c.*, it will be seen that these substances, which include the non-nitrogenous principles soluble in cold water, are present in larger proportion than in rye bread, although they do not exceed what we find in the rye flour. The poverty in starch is therefore partly, but by no means fully, compensated.

It must also be acknowledged that the *nitrogenous matter* in this sample of Russian bread is certainly high; but due regard must be paid to the fact that the leaves and woody tissue which, as will be seen, are present may probably not only introduce some nitrogen, but this in an indigestible form. This brings us to the strange and unjustifiable presence of woody fibre, husk, &c., which occurs to a very large extent. The proportion of this adulteration as compared with good rye reaches the very high figure of 10 per cent. It possesses no food value whatever. Worse still, it is not only itself incapable of digestion by man, but it hinders the digestion of the other constituents associated with it. It is well known that hard ligneous substances, such as the bran of black and brown bread, provoke by mechanical irritation active intestinal peristalsis. Moreover, the addition of cellulose or woody tissue to a meat diet is known to cause an imperfect assimilation of whatever meat may be consumed at the same time. On incineration of the separated fibre a strong smell, very like that produced in an ordinary bonfire or when garden refuse is burned, was evolved. The microscope showed fragments of plant leaves, with husk as well as mineral particles, and small seeds resembling rape. All these substances are of course foreign to genuine bread.

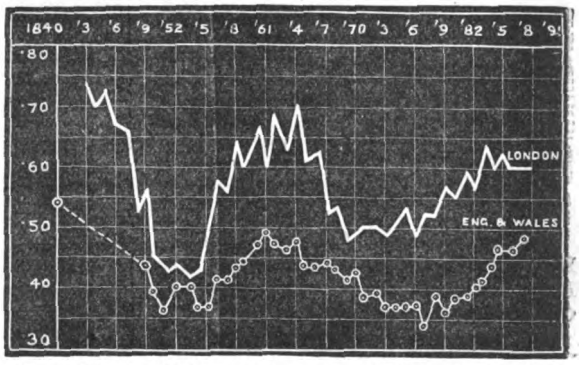
In respect to the *fat*, this item includes also colouring matter. The residue from the ether used in the extraction was of a bright green colour, probably derived from the chlorophyll in the leaves of some plant with which the bread is apparently admixed.

No less than 5·63 per cent. of the Russian bread consists of *mineral matter*, of which nearly one-half is silica and sand, about one-third alkaline carbonate (derived no doubt

Digitized by Google

from the woody matter), and not more than one-fifth valuable phosphatic constituents. The total mineral matter of genuine bread seldom exceeds 1·5 per cent., or 1·8 per cent. at most, while it never contains carbonate. Bread containing as much mineral matter as that in the Russian specimen would be regarded in England as grossly adulterated, and legal proceedings would be immediately and, it might be added, successfully taken in accordance with the requirements of the Food and Drugs Adulteration Act. The husk and leaves in the bread would account for this abnormal result.

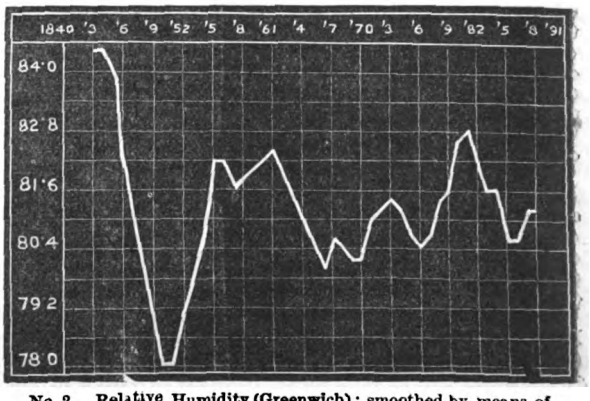
Our examination indicates, in short, the addition in round figures of not less, and probably more, than ten pounds of foreign substances to every hundredweight of rye flour. The foreign substances would appear to consist of certain leafy matter and seeds, including woody fibre and husk.



Thus, to make the flour a little heavier, and to increase its volume, we have foreign matter, husk, leaves, &c., which are not only of no use in themselves, but destroy a portion of the nutritive value of what remains. How much better would it have been to have had in bulk 10 per cent. less bread. A Russian, writing from the same province from which the sample of bread we have analysed was obtained, speaks of much worse specimens than this. He says: "I found in many cases that this so-called bread contained no rye-flour whatever, but was composed of revega (wild arrock), potatoes, chaff, and leaves." Then he adds the terribly significant announcement that "within two versts of my house there are more than 130 cases of typhus. Hunger and cold in their severest forms are daily gaining ground, and pestilence even now is devastating the districts." The Government relief, where it is given, only amounts to 30 lb. of rye-meal per head per month, excluding from each family the father and two of the children, who, according to the Government theory, ought to be able to keep themselves. Most of the cattle has been sold, and this for derisive sums. It will be almost impossible to carry on agricultural operations as in the past. If the weather this year favours a good harvest, there will nevertheless be a renewal of the famine next winter; for, in many cases, it is impossible to procure seed for sowing. For instance, from Volskaya, near Suratoff, we hear there are 280 cultivators, and that not ten among them will have seed. The best of weather, therefore, will fail to produce a good harvest at Volskaya, and there are any number of other places in a similar predicament. We sincerely trust there will be a good harvest this summer, but we fear it will not prevent a renewal of the distress next winter. Doubtless next year's famine will not afflict so many provinces; but the people, so sorely tried now, will be less able to support it. Therefore, in looking upon this question, it is unhappily necessary to make provision for the long continuance of the present suffering. That it will engender plague and pestilence in Russia is but too likely, and it is a question whether these terrible evils may not travel farther, and Russia become a centre of contagion that will spread to other parts of Europe, or perhaps of Asia.

Not the least distressing among all these sad facts is our inability to efficaciously help in this moment of sore distress. We are convinced that the English people would take especial pleasure in showing that no political consideration could in any way lessen their feeling of intense sympathy for the suffering of the Russian people. Unfortunately the oft-demonstrated venality of Russian officials has prevented the sending of subscriptions to the Russian Government; while, on the other hand, the Russian authorities will not allow private charitable organisations to take the matter in hand. Consequently no general appeal has been made, though so many feel that it is the duty of all Europe to come to the rescue of Russia in her present trouble. The Russian Government assumes a heavy responsibility in checking all spontaneous efforts at assistance. It is in the same position as the Spanish Government during the great cholera epidemic of 1885. The Spanish Government officials were not trusted, and little or no money was placed in the hands of the Spanish Government for the relief of the distress. But charitable organisations were formed in Spain by private enterprise, and these commanded the confidence of all. They were the means of relieving much distress, and received liberal support. Nothing of the sort is possible under the Russian autocracy. Thus the few subscriptions which, in spite of these unpromising circumstances, can be collected in England, must be sent, not to a large representative and responsible society, but to individuals, such as Count Tolstoï, or to such Protestant and other clergymen as may be known in England, or to some individual county council or zemstov which the subscriber has special reason to trust. All this is most deplorable, as otherwise it would have been possible to render efficacious relief. In America and in France large sums could be obtained. The Germans have already offered help, and therefore we may most assuredly conclude that many thousand lives could be saved by assistance from England and other countries This would have lessened the danger of epidemics that may not be confined to Russia, and would have done much to soften the antagonisms which unfortunately exist between different countries, and which we must all deplore

ON VARIATIONS IN THE DEATH-RATE OF MEASLES.



BY ALEX. B. MACDOWALL.

IF we take the annual death-rates of measles in London since 1841, and smooth the values by means of five-year-averages, we get the upper curve in the accompanying chart (No. 1). Dealing similarly with the measles death-

No. 1.—Measles Death-rate for London and for England and Wales: smoothed by means of five-year averages. The upper curve refers to London: the lower curve to England and Wales.

rate for England and Wales, we get the second curve. (This series begins in 1838, but there is an interruption from 1843 to 1846.) It will be understood that each year-point represents an average of five years. These curves reveal a curious fluctuation in the death-rate. At

No. 2. Relative Humidity (Greenwich): smoothed by means of five-year averages.

about twenty years' interval, in the case of London (say, in 1843, 1864, and 1883), maxima seem to have been reached, while minima appear in 1853 and 1869. The curve for England and Wales also presents long waves, with

Digitized by Google

apparently somewhat longer intervals between the maxima, one of which was in 1861. We appear to have been lately near the crest of one of those waves, and might perhaps expect the curve now to go down, on the whole, for some years.

Unfortunately we cannot go further back than the dates indicated for exact data regarding the death-rate, but it might be well to study, on the one hand, the relative prevalence of measles in the years previous to 1840 for indications of like intervals, and to watch the future course of the curves in the light of what they indicate during those fifty years.

The third curve (second chart) is one of humidity. The annual figures denoting relative humidity at Greenwich are smoothed in the same way as the death rates. A certain degree of correspondence to the upper curves will be noted. The phases of the London death-rate curve appear, however, to lag somewhat behind those of the humidity curve, as might, perhaps, be expected from the relationship between these two phenomena.

For the sake of comparison I append a few figures, showing the London measles death-rate in two groups of five years, each having a maximum year central, and in two groups, each having a minimum year central.

DEATH-RATES.

UNIVERSITY OF LONDON.

MEETING OF CONVOCATION.

AT the meeting of Convocation of the University of London on the 19th inst. the chair was taken by Mr. E. H. Bush, in the absence through illness of the Chairman of Convocation, Dr. Wood.

A vote of condolence to the Queen and the Prince and Princess of Wales on the occasion of the lamented death of the Duke of Clarence and Avondale was proposed from the chair and unanimously passed.

Dr. W. J. COLLINS, M.D., presented the report of the Annual Committee, and moved its reception. This having been agreed to, Dr. Collins moved the adoption of the following motion (*a*) recommended in Paragraph 8 of the report of the Annual Committee: "That, having regard to certain changes in the regulations for the Honours Examination in Chemistry at the B.Sc Examination, whereby the production of the student's MS. book of laboratory work is required, signed by the teacher, if any, whose course he has attended as evidence of work done under the teacher's direction and supervision, this House is of opinion that such regulation imports into examinations considerations which should be excluded, and is liable to place at a disadvantage the non-collegiate candidates."

Dr. O'REILLY, D.Sc., seconded the motion.

Dr. TILDEN, D.Sc., moved, and Dr. CURNOW, M.D., seconded, an amendment to the effect that Clause 8 of the report should be referred back to the committee for further consideration. After some discussion the amendment was declared to be lost, and Dr. Collins's motion was subsequently carried.

Dr. T. B. NAPIER, LL.D., moved:—"(1) That this House, while not expressing any opinion as to the proposed new Charter for the Albert University generally, yet considers that the absence of any sufficient provision in the Charter for securing a fixed period and definite course of study by candidates for its degrees is likely to prove injurious both to the interests of higher education and of this University; (2) that the annual committee be requested to take such steps as in their opinion may be desirable to obtain a modification of the Charter in this direction; (3) that the annual committee be further requested to represent the views and guard the interests of Convocation generally in all matters connected with the proposed charter, and that for this purpose they be empowered to confer and to take joint action with the Senate, and to act otherwise as may seem expedient." He said that many objected to the proposed Charter of the Albert University as creating a university one-half of which was likely to be of a denominational character. It was opposed to the interests of higher education and also to the interests of their own University. There was no need for another examining University of London. Many might think the matter was really so serious that the Senate should have taken steps against such a Charter, or at least ask that the whole matter should be referred back to the Royal Commission. He was perfectly certain that Convocation had always looked, and would always look, to the Senate to guard its interests, and it was only when Convocation found the Senate listening to every voice, when it found it yielding all the privileges which had made that University such a success as it was at present, that it said it would go no further. He was sure Convocation would unite with the Senate to prevent that obnoxious Charter from becoming law.

Dr. O'REILLY seconded the resolution.

Dr. COLLINS moved as an amendment to Clauses 1 and 2 of the resolution, "That this House is of opinion that the Albert University Charter, if granted, would neither supply a Teaching University for London, as recommended by the Royal Commission, nor tend to promote the interests of higher education, while it might interfere with the work of the University of London. That the chairman be asked to convey a copy of this resolution to Sir John Lubbock, M.P., with the request that he will bring it to the notice of Parliament."

Mr. BUSK seconded the amendment, which was accepted by Dr. Napier in the place of his own motion, and carried as a substantive motion. Clause 3 of the resolution was also carried.

TUBERCULOSIS.

THE Medico-Chirurgical Society of Glasgow have, in pursuance of a resolution passed at a meeting of the Society on Dec. 18th, 1891, addressed a memorial to the Lord Provost, Magistrates, and Town Council of Glasgow in respect to the infectious character of tuberculosis and the need for prophylactic measures.

The following is the main text of the memorial:—

"1. Tuberculosis is an infectious disease in the sense that in all cases of this disease the one constant and necessary element in the causation is a microbe. This microbe grows and multiplies in the bodies of certain animals and of man when introduced from without, and in so doing it produces an intensely active poison which is the more direct agent in bringing about the morbid changes in the living structures. There are doubtless other elements in the causation, such as inherited and acquired susceptibility, but the microbe is the only essential and constant one, and there is evidence to show that, without any special susceptibility, it may produce the disease if introduced in sufficient quantity.

"2. As the microbe will not grow except at a temperature almost identical with that of the body, the living bodies of men and animals affected are the great propagating places of it. They are the sources of the supply, and constitute the centres from which the infection is derived. But the microbe is not retained in the bodies of the persons affected. Most of the forms of tuberculosis are characterised by discharges of matter from the affected parts of the body, and these discharges contain the microbe—often in very large quantities. The most frequent form of tuberculosis is consumption of the lungs, and persons affected with this disease almost constantly spit up matter which is loaded with the infective microbe. The sputum of such persons when dry is liable to be pulverised into fine dust, and this in its dissemination carries the still living microbe with it.

"3. It is believed that tuberculosis is fairly to be compared, as regards its infectious quality, if not with typhus and small-pox at least with typhoid or enteric fever, although the mode and channel of the infection may be so different

Digitized by Google

as to make it much less obviously dangerous to live in the same house or room with a case of consumption than it would be in the case of one of the well-known contagious fevers. Tuberculosis, however, is much more disastrous in its results than all the other infectious diseases put together. According to the annual report of the Registrar-General for 1888, the deaths registered as due to tuberculosis in Glasgow numbered 1824, and those assigned to all other miasmatic—that is, infectious—diseases, including measles, scarlet fever, whooping-cough, &c., were 1089. For reasons know to us, it seems certain that the mortality from tuberculosis considerably exceeds that which appears in the Registrar-General's returns, but even these figures are sufficiently striking. The deaths registered as tuberculous made up 15·5 per cent. of the total deaths in Glasgow in 1888. These facts imply a large amount of what may be called 'floating infection' in our midst.

"4. The Town Council by its action in prohibiting the sale of tuberculous meat and milk has, in our opinion very properly, endeavoured to grapple with one source of the infection. It may be said that the great prevalence of tuberculosis in cattle, especially in milk cows kept in town byres, and therefore both more likely to be infected with tuberculosis and to become in turn sources of infection through their milk, has justly been already considered by the authorities. We recognise the wisdom of a policy having for its object the removal of this source of infection, which is dangerous for man as well as for animals. It should be possible by rigid cleansing and disinfecting of byres, and by the condemnation of all carcases or animals known to be tuberculous, to stop this source of infection.

"5. It is not for us to prescribe the mode in which the infection should be dealt with in the case of man. The Council has skilled officials whom it can consult on the matter. But we venture to suggest that a beginning should be made with a definite attempt to stay the infection. If the public were authoritatively informed of the harmful nature of all discharges from tuberculous persons, and more particularly from cases of consumption of the lungs, and if they were encouraged to have these discharges rendered innocuous, and also to submit their houses and clothing to disinfetcion at intervals during the currency of the disease, and again at its close, it is believed that much good would result. With the splendid sanitary organisation which Glasgow possesses, it should be possible to do much to cleanse our city from some of the principal causes of the widespread prevalence of this its greatest plague."

The document is signed on behalf of the society by

UNIVERSITY LIFE IN AUSTRALASIA.

IN the lecture delivered by Professor Anderson Stuart, M.D., Professor of Physiology in the University of Sydney, the other evening at the Royal Colonial Institute, there was much to interest the profession of medicine, but we shall content ourselves with emphasising one or two points that appear to us well worthy of notice. The universities of Australasia are teaching universities, each one having its staff of professors and other teachers, and in medicine there is no such thing as exemption from lectures. There are at the present moment altogether 141 teachers and 2049 students actively engaged in the work of the universities. The former are for the most part graduates of European universities. The duration of the curriculum in medicine has never been less than five years, and, in Sydney at least, physics, ophthalmic medicine and surgery, psychological medicine and logic, and the principles of science are necessary for the bachelor's degree. The standard of examination is a high one, and nowhere in Australasia is there anything like a "cheap" degree. Dr. Anderson Stuart speaks highly of the work of the students, and says that they "have a definite aim and take a serious view of life." In the University grounds is a general hospital, the Prince Alfred, which is the clinical school for the University. No difference is made between the sexes; there are no separate courses of instruction in Sydney, and no difficulty has made itself felt. The last third of the lecture is exclusively occupied with what appears to be the burning question of the day—viz., that of government. It appears that at present in all the four universities the body of graduates has, or soon may have, the entire management in their hands, inasmuch as they elect the governing body, which controls not only such matters as finance and appointments, but even actively busies itself with questions of internal administration, discipline, and purely educational matters, which it would do very much better to leave to the teachers, whose daily work is concerned with such things. It is proposed, it seems, in some quarters to get rid of the present representatives of the teachers, who sit on the governing body, so that then all the members of the governing body would receive their mandate directly from the graduates. The lecturer argued against the graduates being necessarily fit and proper persons to exercise this power, and spoke in favour of the adequate representation of all the interests concerned—viz: (1) The public, through the Government representatives, all the more since the greater part of the funds come from the State, which at present has no voice in their expenditure; (2) the educated public, through the graduates' representatives; (3) the teachers; (4) the body of students, as in Scotland; and (5) perhaps the affiliated colleges in Sydney and Melbourne. The first three certainly constitute great and important interests, which should be represented in the governing body. With regard to the other two the case is not so clear. The presence of purely business men in the governing body is strongly advocated, and, indeed, the above scheme is largely to that end, for it seems that only professional men at present have any chance of election. Of the expediency of business men being there to advise on the many important business questions that arise there can be no question. Lastly, the lecturer urged that the body of teachers should be more trusted in the actual work of teaching than they are; and he was right. It is very easy to govern too much; and if a governing body is constantly interfering in such matters nothing but mischief can result. The resignation of the Professor of Law and Dean of the Faculty of Law in Melbourne, of which we have just read, comes to give point to the lecturer's words. But still there is no place that is perfect, and, said the lecturer, "Taking it all in all then, so far as our immediate surroundings are concerned, one *may* be very happy in a Colonial University chair. People will certainly be very kindly disposed to one, the authorities will do their best for one according to their lights, and, in a word, here, as so often elsewhere, the place is very much what one makes it. *Es hallt aus dem Walde wieder, wie man hineinruft.*"

INFLUENZA.

THE mortality returns for the week ending Jan. 16th exhibit some curious departures from the usual comparative death-rates in the large towns, which may doubtless be taken as indicating the places where influenza and its concomitants are prevailing or otherwise. Thus in London the death-rate has risen to 40 per 1000, but this proportion is exceeded by Liverpool (42), Wolverhampton (48·1), Brighton (51·5), and Portsmouth (57·5). Four weeks ago the rates at the two last-named places were only 18·0 and 17·9 respectively. The lowest death-rate for the week is at Huddersfield (14·6) and Bradford (15·7).

The deaths directly attributed to influenza in the metropolis for the week amounted to 271, and in addition to these there were 63 cases in which influenza was noted as a secondary cause. The number of deaths from diseases of the respiratory organs was 1248, or 594 above the corrected average. It is noteworthy that in London the total mortality was 1193 above the average numbers in the corresponding weeks of the last ten years, and that the unusual circumstance of there being more deaths (3271) registered than births (2680) is recorded.

Digitized by Google

As regards the prevalence of the disease in this country, we regret not to be able to record any appreciable diminution in its extent, although in some districts it seems to be of a far milder type than in others, or than in the previous outbreak. The accounts from all quarters are much to the same effect—namely, that the disease is still very prevalent. Indeed, it is in marked contrast with the more rapid subsidence of outbreaks noted last year and two years ago that in some places it has persisted, almost undiminished, for the past month or six weeks. Newcastle and Aberdeen are instances of this, the latter city experiencing of late a somewhat serious extension. From Manchester we learn that "cases of influenza have been met with here and in the surrounding districts, but compared with last year's epidemic it is mild and far less prevalent; neither amongst the patients at the hospitals and dispensaries nor in private practice has it assumed anything like serious proportions. At present it has not affected our local mortality to any appreciable extent, and our death-rate has been below rather than above the average." It seems to be more severe at Liverpool, and it has broken out in the Isle of Man, but in mild form. At Carlisle it is very prevalent. In Yorkshire there is also much sickness; and cases continue to occur in Lincolnshire There seems to be no appreciable abatement in Norfolk and Suffolk, Norwich and Bury being especially attacked. Similar reports come from Cambridgeshire, Northamptonshire, Hertfordshire, and Essex. At Leicester the type is mild; but Dr. Tomkins, the energetic medical officer, has issued a circular warning the public of a possible visitation, and giving directions for prompt resort to care and medical advice. At Worcester, Birmingham, Stafford, and other midland districts it is very prevalent. In London and the suburbs it continues unchecked, and the public services are being greatly incommoded, magistrates, police, postal servants, and members of the Fire Brigade being amongst the sufferers. Nor is there apparently any notable diminution in the Kentish towns and villages, especially in the Maidstone and Ashford districts; whilst Sussex and Hampshire (especially Portsmouth and Southampton) are still the seat of the disease. Further west, we hear of its continued prevalence in South Devon, and its outbreak in Somersetshire.

Abroad the epidemic, which had subsided somewhat at Marseilles, has again appeared in severe form; also at Lyons and Chalons. It is abating at Milan, but spreading in Rome. Germany is gradually getting free from it, but its seaports have suffered severely. In Silesia, however, it is very severe. It is about the same at Vienna and is extending in Roumania. In Denmark and Sweden, where it has been exceptionally severe, it is now declining.

DR. BACCELLI ON INFLUENZA.

ON Friday, the 15th inst., writes our Italian correspondent, the amphitheatre of the Santo Spirito Hospital in Rome was crowded by an audience of more than three hundred to hear Dr. Baccelli deliver a lecture on influenza. Besides his own students, there were present the *personnel* of the public sanitary service, medical officers of the army and navy, and many lady nurses, professional and non-professional. The lecture, which lasted an hour (from 11 A.M. till 12), was illustrated as to symptoms and diagnosis by a typical case, carried in on his bed from the wards. Among the salient points of the lecture were the following:—For the last two centuries influenza has appeared in epidemic form about once in every ten years, but in varying degrees of diffusion and severity, and presenting by no means the same features or running the same course. Concurrent cold and wet have in Italy been its favouring conditions, and where it has been milder in its incidence there has been a humid atmosphere, without cold, as in Rome; or a cold atmosphere, without humidity, as in the sub-alpine towns. Rome, indeed, has in the past enjoyed greater immunity from the severer forms of the disease than any other city of the same latitude, thanks to the stillness of her air, as well as to her bland, if moist, climate in winter. Even in this last visitation she has escaped more lightly than any other populous centre of the same size in Europe. The pathogenic microbe recently discovered is the same for all cases of influenza, but its favouring conditions are diverse, and among these must be noted the resisting power of the patient. During the epidemic of the last three years the catarrhal or rheumatoid forms of the disease have been less significant than the neurosal—this latter, indeed, constituting its true culminating character (*vero carattere culminante*). This neurosal character betrays itself not only in the usual points of least resistance—the respiratory and circulatory apparatus, as well as in the alimentary tract,—but throughout the whole system (*per tutto l'organismo*); and it is in subjects who have passed the meridian of life ("*il mezzo del cammin di nostra vita*"), whose breathing and blood-diffusing, as well as blood-forming, apparatus are enfeebled by time and use, that influenza finds its aptest prey. Having described some typical cases of influenza and reviewed the symptoms in the ascending scale of their severity, Dr. Baccelli took one in which there was bronchial distress concurrently with debilitated heart, and indicated the treatment to which the response was most satisfactory. Camphor, whether for its action on the nervous system or its microbicidal virtue, is of marked benefit at the first stage. The labouring heart, announced by the enfeebled, often faltering and irregular pulse, is reinforced by injections of oil of camphor every three or four hours, in doses of twenty-five centigrammes of camphor to one gramme of oil. When the gravity of the symptoms is still unrelieved, or when by previous use of the remedy the patient does not satisfactorily respond to it, the injection of ether often succeeds admirably. In other cases, when impending cardiac failure calls for it, the injection of strychnine, beginning with two milligrammes and ascending to six milligrammes in the twelve hours, will often tide over this crisis and gain precious time. In this direction the neutral sulphate of strychnine has succeeded where the ethereal tincture of castoreum has failed. To sustain the powers, wine (preferably white Capri or Rhenish) taken very hot, in small quantities and at frequent intervals, should be given, and manifest good has been derived from a few centigrammes of Kermes in combination with quinine and camphor. It is not only the mucous, but the gastro-intestinal, zone that may be affected by influenza. In the last epidemic we have had true gastro-enteric forms; and in these we must feel our way with caution. If the patient is young and strong, then there can be no hesitation in employing an emetic—ipecacuanha in small doses by preference. The nervous symptoms are really more formidable than the gastro-enteric. In the acoustic cavities of the head the mucous tract is equally affected, as in other passages; delirium often supervenes, and in these cases, particularly in advanced life, the closest attention must be paid to the heart. When the respiration is embarrassed, striking benefit is often derived from the inhalation of oxygen. This, supplementing the subcutaneous injection of strychnine, is an addition to therapeutics which does honour to the Roman school, where it has long been practised with signal success.

The lecture, of which the above abstract gives but a meagre impression, will, at the request of the students, be made *publici juris*.

CONGRESS OF INTERNAL MEDICINE.

THE programme of the Eleventh Annual German Congress of Internal Medicine, which assembles this year at Leipzig on April 20th, has just been issued. Professor Curschmann is the president, and the permanent secretary is Dr. Emil Pfeiffer of Wiesbaden. Two subjects for general discussion are announced—the one on "The Severe Anæmic Conditions," is to be opened by Dr. Biermer (Breslau) and Dr. Ehrlich (Berlin); the other, on "Chronic Inflammation of the Liver," opened by Dr. Rosenstein (Leyden) and Dr. Stadelmann (Dorpat). There is a long list of papers, which includes the following:—Dr. Emmerich (Munich), Causes of Immunity and Recovery from Infectious Diseases; Dr. Peiper (Greifswald), Uræmia; Dr. R. Binswanger (Krewzling), Results of Treatment by Suggestion; Dr. Goltz (Strassburg), Results of Excision of Large Portions of the Spinal Cord; Dr. Schott (Nauheim), Etio-

Digitized by Google

logy of Chronic Heart Disease; Dr. Fürbringer (Berlin), on so-called Hepatic Colic and Pseudo-calculi (Biliary); Dr. Minkowski (Strasburg), Diabetes Mellitus following Extirpation of Pancreas; Dr. Adamkiewicz (Cracow), Treatment of Carcinoma; Dr. Finkler (Bonn), the Varieties of Pneumonia; Dr. Israel (Berlin), Secondary Changes of Circulatory Organs in Renal Insufficiency; Dr. Landois (Greifswald), Therapeutic Value of Blood-Transfusion in Man; Dr. Rütimeyer (Basel), Bilharzia Disease; Dr. Grawitz (Greifswald), Hæmorrhagic Infarcts in the Lung; Dr. Klebs (Zurich), Recovery from Tuberculosis and Biology of Tubercle Bacilli; Drs. G. and F. Klemperer (Berlin and Strasburg), Researches on Causes of Immunity and Recovery, especially in Pneumonia; Dr. Buchner (Munich), Immunity against Infectious Diseases; Dr. von Ziemssen (Munich). Subcutaneous Transfusion of Blood; Dr. H. Leo (Bonn), Diabetes Mellitus; Dr. Schreiber (Königsberg), Disorders of the Renal Circulation. Other papers are promised by Drs. Gerhardt, Geppert, Wolft, Löffler, Stern, von Jaksch, and Vucetic. The local secretary of the Congress is Dr. Krehl, Leipzig, Thalstrasse, 31.

RAILWAY ACCIDENTS IN 1891.

THE report upon railway accidents recently issued from the Board of Trade shows that the casualties attending this industry have been happily both fewer and less serious in their consequences than has been the case on many previous occasions. Indeed, when the record of six months contains no single instance of a railway passenger killed in any accident due to the movement of trains, it is possible to take a very pleasing view of the degree of perfection to which the working of our railway system has been brought. Nor is it only in respect of the immunity from accident which the present return exhibits that matter of congratulation may be found. It is only less gratifying to discover from an examination of the record of accidents that the lesson of experience has been taken to heart, and that errors which have proved to be the fruitful sources of disaster are being one by one corrected. Thus it is eminently satisfactory to find in the present record much less evidence than has usually been forthcoming of the literally fatal effects of overwork and protracted hours of labour. The examiners very properly are careful to inquire into this point and systematically to report the result of their inquiries. But it does not appear that the accidents which have formed the subject matter of the inquiries dealt with in the Blue-book have been in any appreciable manner attributable to this cause. In one or two instances the inquiry on this head has elicited the fact that railway servants are still to some extent overworked, but the extent of this overwork has not been great, nor has it in any instance been a manifestly contributing cause of accident. It is therefore very evident that in this respect the expression of public opinion has had a most salutary effect, and it may be hoped that at no distant date the chronicler of railway annals will be able to report the practical removal of what was at one time the most serious grievance of railway men and the most formidable danger to the public to which the railway system had given rise.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6420 births and 6455 deaths were registered during the week ending Jan. 16th. The annual rate of mortality in these towns was equal to 33·0 per 1000, against 28·7 in the preceding week; in London the rate was as high as 40·0 per 1000, while it averaged 28·0 in the thirty-two provincial towns. The lowest rates in these towns last week were 14·6 in Huddersfield, 15·7 in Bradford, 17·1 in Leicester, and 19·2 in Halifax; the highest rates were 42·0 in Liverpool, 48·1 in Wolverhampton, 51·5 in Brighton, and 57·0 in Portsmouth. The 6455 deaths included 604 which were referred to the principal zymotic diseases, against 549 in the preceding week; of these 265 resulted from whooping-cough, 161 from measles, 53 from diarrhœa, 52 from "fever" (principally enteric), 43 from diphtheria, 29 from scarlet fever, and one from small-pox. No fatal case of any of these diseases was registered in Plymouth, in Huddersfield, or in Halifax; while they caused the highest rates in Bolton, Sunderland, Newcastle-upon-Tyne, and Swansea The greatest mortality from measles occurred in Burnley, Liverpool, Gateshead, Derby, Swansea, Sunderland, and Newcastle-upon-Tyne; from scarlet fever in Swansea; from whooping-cough in West Ham, Wolverhampton, London, Swansea, Bolton, and Newcastle-upon-Tyne; from "fever" in Norwich, Salford, Derby, and Bolton; and from diarrhœa in Sunderland. The 43 deaths from diphtheria included 29 in London, 2 in Birkenhead, 2 in Leeds, and 2 in Newcastle-upon-Tyne. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three great towns; five small-pox patients were under treatment in the Metropolitan Asylum Hospitals, and 1 in the Highgate Small-pox Hospital. The number of scarlet fever patients in the Metropolitan Asylum and the London Fever Hospitals at the end of the week was 1391, against numbers declining from 1554 to 1435 at the end of the preceding six weeks; 92 new cases were admitted during the week, against 101 and 104 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 553, 1317, and 1084 in the preceding three weeks, rose last week to 1248, and exceeded by 594 the corrected average. The causes of 129, or 2·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Bolton, Burnley, Sunderland, and in three other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Preston, Bradford, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined in the preceding three weeks from 27·1 to 24·9 per 1000, further fell to 23·9 during the week ending Jan. 16th, and was 9·1 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·1 in Paisley and 17·1 in Leith to 31·4 in Greenock and 38·1 in Perth. The 664 deaths in these towns included 16 which were referred to whooping-cough, 12 to diarrhœa, 7 to scarlet fever, 6 to "fever," 5 to diphtheria, 4 to measles, and not one to small-pox. In all, 50 deaths resulted from these principal zymotic diseases, against 69 and 58 in the preceding two weeks. These 50 deaths were equal to an annual rate of 1·8 per 1000, which was 1·3 below the mean rate last week from the same diseases in the thirty-three English towns. The fatal cases of whooping-cough, which had been 22 in each of the preceding two weeks, declined to 16 last week, of which 9 occurred in Glasgow and 5 in Aberdeen. The 12 deaths from diarrhœa exceeded the number in any recent week, and included 7 in Glasgow. The fatal cases of scarlet fever, which had been 9 and 4 in the previous two weeks, rose again to 7 last week, of which 5 occurred in Glasgow. The 6 deaths referred to "fever" corresponded with the number in the preceding week, and included 2 in Edinburgh. The fatal cases of diphtheria, which had been 11 and 8 in the previous two weeks, further declined to 5 last week, of which 3 occurred in Leith. The 4 deaths from measles were all recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 254 to 200 in the preceding three weeks, rose again to 226 last week, and were within 2 of the number in the corresponding week of last year. The causes of 67, or 10 per cent., of the deaths in the eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 45·8 and 35·0 per 1000 in the preceding two weeks, rose again to 43·8 during the week ending Jan. 16th. During the thirteen weeks of last quarter the death-rate in the city averaged 29·8 per 1000, against 20·5 in London and 25·5 in Edinburgh. The 294 deaths in Dublin during the week

Digitized by Google

under notice exceeded by 59 the number in the previous week, and included 5 which were referred to whooping-cough, 3 to diarrhœa, 2 to "fever," and not one either to small-pox, measles, scarlet fever, or diphtheria. In all, 10 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1·5 per 1000, the rate during the same period being 4·1 in London and 1·2 in Edinburgh. The fatal cases of whooping-cough, which had steadily increased in the preceding six weeks from 2 to 10, declined again to 5 last week. The deaths referred to different forms of "fever" (principally enteric), which had been 10 and 5 in the previous two weeks, further declined to 2 last week, a lower number than has been recorded in any week since the beginning of September last. The 294 deaths registered in Dublin last week included 48 of infants under one year of age, and 107 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded those recorded in the preceding week. Ten inquest cases and 9 deaths from violence were registered; and 80, or more than a fourth, of the deaths occurred in public institutions. The causes of 31, or nearly 11 per cent., of the deaths in the city were not certified.

THE SERVICES.

Surgeon-Captain M. T. Yarr has joined the 2nd Battalion Coldstream Guards for duty as an attached medical officer.

INDIAN MEDICAL SERVICE.—*Bengal:* To be Brigade Surgeon-Lieutenant-Colonels: Surgeon-Lieutenant-Colonel Denis Francis Keegan, M.D. (dated Aug. 11th, 1891); Surgeon-Lieutenant-Colonel Stephen Coull Mackenzie, M.D., (dated Aug. 13th, 1891) (these promotions cancel those made in the *London Gazette* of Nov. 27th, 1891); Surgeon-Lieutenant-Colonel Thomas French-Mullen, M.D. (dated Sept. 2nd, 1891).—Surgeon-Captains to be Surgeon-Majors (dated Oct. 31st, 1891): George William Patrick Dennys, John William Unthank Macnamara, M.D., Joseph Sykes, and John Francis Tuohy, M.D.—*Madras:* To be Brigade Surgeon: Surgeon-Major James Byers Thomas (dated April 30th, 1889) —Surgeon-Captains to be Surgeon-Majors (dated Oct. 31st, 1891): James Cort Marsden, Francis Casement Reeves, John Leopold Poynder, and John Hoey.—*Bombay:* Surgeon-Captains to be Surgeon-Majors (dated Oct. 31st, 1891): Frederick Burness and Charles Fancourt Willis, M.D.

BENGAL MEDICAL ESTABLISHMENT.—The Queen has approved of the retirement from the Service of the undermentioned Officers:—Brigade Surgeon John Duncan, M.D. (dated June 16th, 1891); Brigade Surgeon-Lieutenant-Colonel Henry Potter, M.D. (dated Nov. 2nd, 1891); Brigade Surgeon-Lieutenant-Colonel Rajendra Chandra Chandra (dated Oct. 18th, 1891).

NAVAL MEDICAL SERVICE.—The following appointments have been made at the Admiralty:—Surgeons: Geo. Edmunds to the *Assaye*, and Richard C. Munday to the *Plassy* (both dated Jan. 23rd, 1892); Mr. Philip G. Borrowman to be Surgeon and Agent to the *Elie*, Fife, N.B. (dated Jan. 14th, 1892).

VOLUNTEER CORPS.—*Artillery:* 3rd Middlesex: Surgeon-Captain and Honorary Surgeon-Major J. Cook, M.D., to be Surgeon-Major (dated Jan. 16th, 1892).—*Royal Engineers* (Fortress and Railway Forces): 1st Aberdeenshire: Surgeon-Lieutenant J. J. Y. Dalgarno, M.B., to be Surgeon-Captain (dated Jan. 16th, 1892).—1st Volunteer Battalion, the Buffs (East Kent Regiment): Surgeon-Lieutenant S. Wacher to be Surgeon-Captain (dated Jan. 16th, 1892).—*Rifle:* 3rd (Dundee Highland) Volunteer Battalion, the Black Watch (Royal Highlanders): Surgeon-Lieutenant W. Kinnear, M.B., to be Surgeon-Captain (dated Jan. 16th, 1892).—2nd Volunteer Battalion, the Manchester Regiment: Surgeon-Lieutenant T. Carr to be Surgeon-Captain (dated Jan. 16th, 1892).

SUPERANNUATION.—Dr. Junius Hardwicke, of Chilton Lodge, Rotherham, ex-medical officer of the workhouse, has been awarded by the Rotherham Board of Guardians a retiring pension of £40 a year.

Correspondence.

"Audi alteram partem."

THE BEARING OF RECENT BIOLOGICAL RESEARCH ON THE PRACTICE OF MEDICINE AND SURGERY.

To the Editors of THE LANCET.

SIRS,—Dr. Molloy really supplies his own answers to the question or objection propounded in his letter addressed to THE LANCET of Jan. 16th. It may, however, be pointed out that the passage quoted at the top of the second column of page 13 might have explained this matter in itself had it been read with even moderate care—viz., "We must ascribe the statement so frequently made, that although the treatment with iodine and with other irritants exerts a checking influence as a whole, yet at some point or other the affection still continues to spread." This surely makes it clear enough that the old fashioned remedies, iodine and nitrate of silver, are not thought of as being used for the first time in the treatment of erysipelas; whilst the context shows that what it is specially wished to bring out is that the *rationale* of the treatment by caustic rings was not then understood, and that such treatment frequently failed even in the hands of most experienced surgeons because the pathology of the disease had not been properly worked out; but that now this has been done and the remedy can be properly applied, the results obtained, instead of being irregular and to a great extent accidental, are in the highest degree satisfactory. All I am contending for is that every fresh advance in biological (using the term in its widest sense) research has its influence on the treatment of disease.

I am, Sirs, yours truly,
GERMAN SIMS WOODHEAD.

SIRS,—In common with Dr. Molloy, I had been taught to regard painting the edge of the inflammatory area of erysipelas as valueless, save for showing how much the inflammation spread or receded in the course of a definite number of hours. Personally, I believed it to have as little effect on the erysipelatous process itself as Sydney Smith's famous patting the dome of St. Paul's would please the Dean and Chapter. The external treatment of erysipelas which has seemed to act most powerfully and beneficially on the career of erysipelas has been that recommended by Dr. Royston Fairbank (quoted by Dr. Ringer) of making an application of digitalis in some form or other to the inflamed surface. I generally paint freely with the tincture, and have several times seen how the part painted has shrunk while the other unpainted parts have gone on swelling. Also it affords considerable comfort to the patient, and demands no skilled attention. The action depends, I suppose, on the contraction of the arterioles by the drug, thus controlling and checking the inflammation. How this can be brought into line with recent bacteriological research will be interesting to see.

I am, Sirs, yours very faithfully,
Lincoln. E. MANSEL SYMPSON, M.D.

PATHOLOGICAL CONDITIONS IN THE MAMMA ASSOCIATED WITH CANCER.

To the Editors of THE LANCET.

SIRS,—The valuable contributions to our knowledge of the pathological conditions of the breast associated with cancer given at the last meeting of the Pathological Society by Messrs. Johnson and Beadles would, I think, have been more complete had reference been made to the work of previous investigators, the accuracy of whose observations they have so fully confirmed. Mr. Beadles' remark that, after careful research into the literature of the subject, he had only found some allusions to it by Cornil and Creighton surprises me. These conditions—to which, since Heidenhain's classical researches, so much attention has been directed—were perfectly familiar to Sir Astley Cooper. He says[1]: "I would observe that the scirrhous

[1] Lectures on Surgery, 1819, p. 386

Digitized by Google

tumour is not all the disease; there are roots which extend to a considerable distance, and those who gave this disease the name of cancer probably knew more of its nature than we are disposed to give them credit for. It is supposed by some that this name was given on account of the appearance of the surrounding veins. I should rather say that it was from the appearances on dissection than from anything without. When you dissect a scirrhous tumour you see a number of roots proceeding to a considerable distance, and if you remove the tumour only, and not the roots, there will be little advantage from the operation."

Moreover, Sir Astley Cooper was also well aware that mammary cancers not unfrequently originate in outlying or sequestrated lobules of the glands. On this subject he says[2]: "The margins of the breast do not form a regular disc, but the secreting structure often projects into the surrounding fibrous and adipose tissue, so as to produce radii from the nipple of very unequal lengths; hence a circular sweep of the knife cuts off many of its projections, spoils the breast for dissection, and in surgical operations leaves much of the disease unremoved." I have shown elsewhere[3] that 9·8 per cent. of all breast cancers and 14 per cent. of adenomas originate in this way, quite outside the normal mammæ. Heidenhain[4] has conclusively demonstrated that every mamma containing a cancerous tumour is diseased throughout. Its secreting cells are unduly numerous, and they everywhere show signs of excessive reproductive activity; while the peri-acinous connective tissue is much increased and infiltrated with small round cells. Heidenhain maintains that proliferating acini of this kind left behind at the primary operation are the germs whence late recurrences originate. Moreover, he has shown that the loose areolar tissue which separates the mammary gland from the pectoralis major muscle contains numerous glandular offshoots and lymphatics which in cases of cancer are nearly always diseased. Heidenhain found, on careful examination after removal, that the disease had not been completely extirpated from this situation in twelve out of eighteen breasts consecutively amputated for cancer, and he therefore predicted recurrences, which soon followed. To obviate this he recommends that the fascia over the pectoralis major muscle and a layer of the subjacent muscular fibres should be removed in every case destined for operation, and I have no doubt whatever that his recommendation ought to be regarded as an essential feature of the operation. I am, Sirs, yours truly,

W. ROGER WILLIAMS, F.R.C.S.

THE LATE DEATH UNDER CHLOROFORM AT UNIVERSITY COLLEGE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I beg to hand you the following particulars of the case of death under chloroform which occurred at University College Hospital on the 6th inst.:—Patient was a man aged forty-eight years, very large build, with an immense amount of adipose tissue. In December, 1889, he had the anterior part of the tongue and a portion of the jaw removed by Mr. Barker for cancer. On that occasion he took the chloroform very well. Patient was readmitted on the 4th inst. for recurrence of the disease in the root of the tongue and in the floor of the mouth. On the 6th inst., patient's general condition being fairly good, chloroform was administered on lint. Patient did not breathe well from the first, but held his breath and strained a good deal. When partially under the influence of the chloroform Junker's apparatus was substituted for the lint. Shortly after this the breathing suddenly failed, the respiratory movements becoming shallower, and cyanosis very marked. The anæsthetic was at once stopped, and after a minute or two the breathing and colour improved. The anæsthetic was again given, but in a very short time the breathing again became difficult, there being slight stertor at first with marked cyanosis, and then very rapidly the respiratory movements ceased altogether. The mouth was opened and the root of the tongue with difficulty pulled forwards and the chin drawn up. This did not cause any attempt at respiratory movement. The back of the throat was sponged out and some blood and mucus cleared from it. Artificial respiration was resorted to, and afterwards laryngotomy was performed, but owing to the patient's large build and rigid thorax the former procedure was not very satisfactory. The pulse could be felt in the temporal artery at the time the respirations ceased. It seems probable that some blood from the growth in the mouth got into the upper part of the larynx at the beginning of the patient's serious symptoms, and that this was followed by respiratory failure. At the post-mortem examination marked fatty degeneration of the heart and cirrhosis of the liver were found.

I am, Sirs, yours faithfully,

WALTER W. H. TATE,
Resident Medical Officer.

London, W.C., Jan 10th, 1892.

A SUGGESTION FOR THE TREATMENT OF IRREDUCIBLE INTUSSUSCEPTION OF THE BOWELS.

To the Editors of THE LANCET.

SIRS,—I have read with much interest Mr. Arthur Barker's paper upon the above subject, the more so as it describes an operation for the relief of certain forms of intussusception of the intestine which is in principle the same as I have advocated in my lectures on intestinal obstruction for the last two or three years, and which, in my work on "Surgical Diseases of the Intestine," now in the press, I have fully described and illustrated. Mr. A. Barker will be interested to hear that last year, in conjunction with Dr. Morrotti, I made a series of experiments with a view of testing the feasibility of the operation. All these experiments, three in number, were successful. The steps I adopted were as follows: In the first place, I created an artificial intussusception, and allowed this to exist from six to ten days before operating for its relief; at the end of this time I found the invagination firmly adherent at the point at which the intussuscipiens receives the intussusceptum; the former was somewhat congested and œdematous. I made a longitudinal incision into the intussuscipiens on the side furthest from the mesentery, directly over the intussusceptum, about an inch and a half long, so as to allow of my being able to have a good view of, and sufficient room to cut, the intussusceptum across through the opening. I next seized the invaginated piece of intestine with vulsellum forceps and snipped it across about half an inch from the proximal end, catching up and tying any vessel that needed it, then with a series of interrupted sutures stitched the divided ends of the stump around, and returned it into the intestine, closing the longitudinal opening in the intussuscipiens with a double row of chromic gut sutures. This operation, although the same in principle as that described by Mr. Barker, differs in one or two material points. First I used no sutures to unite the bowel at the point at which the intussuscipiens receives the intussusceptum, as I found the intestine firmly adherent at this point already; even if this should not be the case, three or four quill sutures would, I think, be quite sufficient to prevent any fear of accident arising from the slipping out of the intussusceptum, as the divided ends were firmly united by a number of interrupted sutures, which should be quite sufficient to secure firm union. With respect to sutures, I invariably use chromic gut for all intestinal suturing, whereas Mr. Barker still uses silk sutures, and for suturing the stump he used stout silk. This, in my opinion, is not devoid of danger in the future. The chromic gut, in my experience, lasts quite long enough to allow of firm union of the peritoneal surfaces. It is then absorbed, and no further trouble can arise, whereas silk will remain an indefinite time, or until it ulcerates out and passes away. This has been proved in one case of gastro-enterostomy, which died over four months after the operation, and the silk sutures were found hanging in the stomach. The same thing were found in Mr. Barker's case of gastro-enterostomy, when 2¾ in. of silk thread were found hanging from the artificial opening into the stomach seven weeks after the operation of gastro-enterostomy. I think the method of dividing the intussusceptum *in situ* is preferable to attempting to draw it out of the incision in the intussuscipiens and then dividing it, as there is less risk of

Digitized by Google

injuring the intestine, already weakened, by tearing or bruising.

To Mr. Arthur Barker undoubtedly is due the credit for having suggested this operation at the Royal Medical and Chirurgical Society in 1887, although until he drew attention to it I was unaware of his suggestion. Professor Senn, also, in the *Canadian Practitioner* for August, 1891, has suggested a similar plan of treating certain forms of irreducible intussusception.—I am, Sirs, yours faithfully,

FREDK. BOWREMAN JESSETT.

Upper Wimpole-street, W., Jan. 11th, 1892.

INFLUENZA.

To the Editors of THE LANCET.

SIRS,—I shall feel obliged if you will allow me to state, in answer to numerous inquiries from medical practitioners, that I consider salipyrin (salicylate of antipyrin) the most effective remedy for combating the feverish attack of influenza. Salipyrin, the properties of which have been studied chiefly by P. Guttmann, Von Mosengeil, Hennig, and others, is a white crystalline powder which is nearly insoluble in water, but soluble in alcohol, and has the composition $C_{18}H_{19}N_2O_4$. It may be given in powder or in a mixture, which should be well shaken, with tincture and syrup of orange peel. The average dose is fifteen grains, which should be repeated at first every two hours. After four or five such doses have been given, there is in most cases an extraordinary change for the better; and if continued afterwards at less frequent intervals, the patient progresses rapidly towards recovery. I have given it chiefly in protracted and alarming cases where antipyrin and phenacetin had already been administered, and where, in spite of these remedies, the fever, prostration, and somnolence were becoming aggravated. The drug appears to have no injurious influence on the heart and other important organs; indeed its beneficial effects on the pulse have been most marked. I need not add that every case has to be treated on its own individual aspects, but think that salipyrin will be found to prove our sheet-anchor in the treatment of the feverish attack of grip. I am, Sirs, yours faithfully,

Jan. 15th, 1892. JULIUS ALTHAUS, M.D.

To the Editors of THE LANCET.

SIRS,—Seeing in your columns a theory put forward by Dr. Althaus, to the effect that the influenza poison attacks chiefly the centres of the bulb, I tried to imagine a clinical picture of such a disease, with this result. The patient is suddenly seized with one or a combination of the following symptoms: choking, loss of voice, fainting, dyspnœa, general flushing or pallor of skin, perverted action of iris, glycosuria. In the cases of recovery from the first seizure the symptoms begin to remit, and during their cessation the patient feels quite well and is desirous and capable of performing acts of great mental and physical exertion. The total absence of pain throughout is a remarkable feature of the disease. It is difficult to recognise any likeness between such an attack and the present epidemic. Yet there is little doubt that influenza does act with disproportionate severity upon the nerve centres compared with other fevers. But this it does generally pretty much inversely according to their stability, the vital centres being as a rule least affected, for influenza is usually a mild disorder. When, however, bulbar symptoms do occur, they are very striking, and are apt to draw the attention from te hmore typical and common symptoms. With respect to treatment, considering the depressing nature of the disease, is the routine prescription of such depressing drugs as antipyrin and salicylate of soda justifiable? The pains of the disease are usually quite bearable when the patient is at rest, as he should be, and pyrexia is seldom a cause of alarm. I would contend, therefore, that the use of antipyrin as a rule should be restricted to those cases in which the pain is unbearable or when hyperpyrexia is present. I am, Sirs, yours faithfully,

THOS. GLOVER LYON.

To the Editors of THE LANCET.

SIRS,—The almost undisputed fact that influenza is contagious seems to be drawing us away from the, to my mind, equally incontrovertible fact that the contagium is air borne, and, though hitherto not indubitably detected, is nevertheless almost certainly a pathogenic germ. The practical consequence of any such error in our efforts to combat the ravages of this disease is obvious. I have already several times (thanks to your courtesy) recapitulated the evidence in favour of an air-borne contagium; the suddenness of invasion, the numbers simultaneously attacked, the fact of crews far out at sea being affected, all point to this conclusion. But a curious misapprehension seems to exist that this theory is incompatible with personal infection. So far from this being the case, the two theories—or, rather, facts—fit one another exactly. The contagium is at first always air borne, but each person as he is infected becomes a fresh nidus, or hotbed of contagion, because fresh spores are generated in enormous numbers in his body, and are of course most numerous and virulent in his immediate vicinity. In this sense influenza is undoubtedly infectious, but not the less is the contagium aerial. Another fact which is in danger of being overlooked is the extreme frequency, I had almost said universality, of pneumonic congestion in influenza. One would naturally expect in an air-borne contagium that the respiratory tract would be the first affected, and this is precisely what occurs, I believe, in almost every instance—a typical pneumonic dulness, a slight hepatisation, may be detected, if only it be diligently sought; so frequently is this the case that I am disposed to regard influenza as an epidemic pneumonia. When the lungs are not implicated the bronchial passages or the mucous surfaces of the eyes or nose are often affected, and not unfrequently the intestinal tract. The intense nervous prostration which is so characteristic of true influenza is not, I believe, the primary affection, but rather the result of the poisonous action of the pathogenic spores on the organism. The interesting letter of Dr. Alfred Carpenter, in your issue of Nov. 21st, affords evidence strongly confirmatory of that quoted in my communication of Nov. 14th on the etiology of influenza as to the mycotic origin of the disease. Another interesting point to which I should like again to call attention is the profound effect produced by the influenzal poison on other concurrent illness. It will be found that during epidemics of influenza all diseases are liable to assume a lower, graver, and more adynamic type, the nervous system being especially depressed. It is for this reason that so long and varied a list of symptoms have been ascribed to influenza. These ought rather to have been assigned to an infinite variety of diseases modified by the depressing action of the superimposed influenza. I am, Sirs, yours truly,

Folkestone. CHARLES EGERTON FITZGERALD, M.D.

To the Editors of THE LANCET.

SIRS,—It is said, and most truly, that the experience of most in our profession is lost because it is never given publicity, and we carry our knowledge to our graves and bury it with our bodies. I am therefore induced to relate the following case. Last April I had a sharp attack of influenza and had to go away, leaving my son in charge of my practice. He took the disease, and worked very hard for ten days with it, when I returned; then he caught a chill, was attacked with severe catarrh of the bowels, with copious diarrhœa; this lasted for forty-eight hours. Then suddenly he was seized with double pneumonia and pleurisy in left side; great cardiac disturbance, with irregular, running pulse, which could not be counted; respiration 40, temperature 103°; countenance anxious, features pale, pinched. I applied immediately a large liquid fly blister to the left side, prescribed sulphate of ether and digitalis, with brandy and beef-tea, and sent for a medical friend at once. He gave me little hope; the case looked desperate. I proposed hypodermic injection of morphia and atropia. This, he said, would kill him, and he implored me not to venture on such a strong measure under the circumstances. There was great restlessness, and my son asked for the morphia to be given. My friend said "This life is so valuable, and is in such terrible danger, I wish to send for Dr. ——," and telegraphed for him to come as soon as possible; but meantime something must be done, and done at once. I believe with Dr. Samuel Wilks in the power and value of opium in all acute inflammatory conditions, and on my own responsibility I injected one-third of a grain of morphia and one-hundredth of atropia at 10 o'clock; every hour or hour and a half he

Digitized by Google

had one ounce of brandy, with four ounces of strong soup. The blister acted splendidly, and the morphia allayed the general irritability almost immediately. Pulse improved; respiration slower; lungs no better; consolidated to a large extent. During the following twenty-four hours he had about three-quarters of a bottle of the very finest brandy. The following morning we three doctors met. The case still looked hopeless, and my conduct regarding the morphia was spoken of as being bold, and that they dared not have used it. That night I injected half a grain of morphia and one-hundredth of a grain of atropia at 10 P.M. At 1 A.M. he awoke greatly relieved, after a quiet, refreshing sleep, all symptoms yielding; expectoration very difficult, the matter being tenacious, mucous, and bloody. Slept till four, and felt so much better that I left him with his experienced nurse. For a week he expectorated large quantities of bloody mucus, which was only dislodged by violent efforts. He made a perfect recovery, and in a month's time there was not a trace of any of the fearful symptoms he had suffered from. I am as convinced that the morphia injections saved life in this case as I am of the fact that I am writing at this moment; had I followed the advice of my *confrère*, which was to administer thirty grains of sulphonal and wait for two hours, I firmly believe death must have followed. In such a case sulphonal or sawdust would have been of very much the same value, and I question if the usual dose of morphia would have been of greater. The large dose acted not only as a sedative to the brain, but as a tonic to the pneumonic and cardiac nerves, and thereby gave the heart and lungs the help they stood so much in need of.

I am, SIRS, yours truly,

Harrogate, Jan. 19th, 1892. A. S. MYRTLE, M.D.

THE INFLUENZA AND SMOKE.

To the Editors of THE LANCET.

SIRS,—Having at the commencement of the present month suffered from a very severe attack of influenza, which for some days confined me to my bed, and for many days to my room, I was led for the sake of occupation to take out my microscope with a view to the examination of the bronchial secretions. Using a Zeiss $\frac{1}{12}$ oil immersion, I found that micrococci, which may not infrequently be found in small numbers, were exceedingly prevalent in the discharge. What, however, I desire particularly to call attention to is the following fact. I live in a very smoky district of a very smoky city, and naturally much carbon enters the lungs in the form of finely divided smoke and coal-dust. For some reason this carbon is not equally scattered throughout the bronchial secretions, but becomes aggregated into comparatively dense patches. Now, wherever these carbon patches were the most dense, there were the micrococci most numerous, sometimes being concentrated in such quantities as to form a zooglœa-like mass of carbon and cocci mixed.

The conclusion I drew from these examinations, which were frequently repeated, was the fact that carbon in a very minute state of subdivision may, and probably does, favour the development of certain forms of micro-organisms. I am not prepared to say that the micrococci I saw were pathogenic, but it is clear that if they were so the conditions favouring their development are specially to be found in our large and smoky cities; and thus we may to some extent account for the increased mortality from epidemic diseases of the respiratory organs when they occur in these localities. For instance, last week in Newcastle-on-Tyne the mortality reached the appalling figure of 45 per 1000, there being an increase in the number of deaths from diseases of the respiratory organs in the proportion of 53 to 17, which was the weekly average for 1890. Living amongst a mining and coal working population I have long had an idea that there was some cause which rendered them specially liable to diseases of the respiratory tract, especially when these occur in an epidemic form; also to other infectious and suppurative diseases which are now generally supposed to bear some relation to the existence of certain micro-organisms. Perhaps it is in the direction above suggested that it may be found. My attention is daily being directed to the extraordinary frequency with which the most trivial corneal wounds lead to destructive suppuration, not in the subjects of broken down and diseased constitutions only, but in vigorous young men in the prime of life. These disastrous results are quite out of proportion to anything we meet with in the same class of accidents occurring in the ordinary civil population, and must have some special cause, if we could but find it out. Possibly it may lie in the direction of the influence of carbon in a state of minute subdivision upon the development of micro-organisms, if this can be established as a fact. I do not know if anyone has already made such a suggestion, but I think it is a subject which might repay the attention of some experienced practical bacteriologist.

I am, Sirs, yours faithfully,

CHRISTOPHER S. JEAFFRESON, M.D., F.R.C.S.EDIN., F.R.M.S.

Newcastle-on-Tyne, Dec. 31st, 1891.

FOOD INTEMPERANCE: HYPERPHAGY, POLYPHAGY, OPSOMANIA, SITOMANIA.

To the Editors of THE LANCET.

SIRS,—My attention having been a good deal directed of late to various abnormalities in the matter of taking food (independently of the Christmas season), I venture to think that the following few remarks on some of them may prove to be not without interest to your readers. So important a subject as intemperance in food, and the consequences which ensue thereon, has not hitherto, so far as I am aware, received the attention which it deserves, although the kindred vice or malady—call it as you will,—intemperance in drink, has probably received more than its due share of public attention. The columns of the leading journal lately bore voluminous testimony to this, and although the subject is quiescent for the time, we shall probably not have long to wait for a renewal of newspaper strife, and an attempt to determine the acceptability and the virtues, or otherwise, of the two-ounce allowance. A consideration of the subject of food intemperance somewhat naturally leads to the sub-division which I have placed at the top of this letter. Abstinence from food and the various causes which conduce to it, having already been dealt with by me elsewhere, are here omitted.

The hyperphagist is met with every day and everywhere; indeed, I fear we are all more or less hyperphagists, and consume a great deal more food at each meal than is at all good for us, or necessary for the physiological requirements of repairing waste and maintaining nutrition at its proper standard. Few of us have the courage to stop short of satiety, and no doubt many minor ailments—nay, even some of the major—are directly due to hyperphagy.

The pronounced glutton—the polyphagist, as I venture to name him—is, fortunately, more rarely met with. The man who gorges himself with food for the mere pleasure of doing it is not a desirable object to witness, but in its many and more modified forms polyphagy, as everyone knows, is not an uncommon vice.

Closely allied to polyphagy is another, and, as many will think, a more excusable vicious practice, to which I would refer as opsomania. It is an overpowering desire to indulge in dainties and sweets to excess. It is often surmised—I am sure with injustice—that ladies are especially prone to this malady.

But perhaps the most rare as well as the most interesting food abnormality, or intemperance, from a psychological point of view, is that which remains to be described, and which for want of a better name I shall call sitomania. Some such definition as the following may be applied to it. "A mania occurring periodically, characterised by loss of volition and an overwhelming desire to partake of food to an unlimited extent, followed by remorse, depression, and tendency to suicide." In many respects this form of disease resembles the now well-known and defined disease dipsomania. In both there are intervals, often prolonged, during which an entirely normal state prevails; there is no undue desire in the one case for excess of food, in the other case for drink. Then, often suddenly, there ensues a wholly uncontrollable desire in the one case for a food gorge, in the other for a drink excess; in both the essence of the disease is the secretiveness with which the orgie is conducted; there also ensues in both, when the orgie is over, the same feeling of intense depression and remorse, and in some cases a tendency to

Digitized by Google

suicide. The sitomaniac adopts much the same means of gratifying his desires as those adopted by the dipsomaniac. When the attack is impending, he, a gentleman of high honour at all other times, will condescend to acts of indescribable meanness and deceit; he will rob his best friends, indulge in petty pilfering, even sell the clothes off his back, and reduce himself to absolute poverty to find the means for this morbid indulgence in food.

I am, Sirs, your obedient servant,

West Malling, Kent, Jan. 9th, 1892. JAMES ADAM, M.D.

THE MEDICAL DEFENCE UNION.

To the Editors of THE LANCET.

SIRS,—The report of the meeting of the Medical Defence Union on Jan. 7th, sent to you by Dr. Leslie Phillips, is very inaccurate, to say no more. The meeting was as far as possible from being "representative," and was very badly attended, consisting almost exclusively of a handful of local doctors. Again, the statement that I "reflected upon the president and council" &c. is simply untrue. With regard also to the statement put into the mouth of Dr. Saundby, accusing me of imputing "mala fides" (which, being interpreted, is bad faith) to my colleagues and making unfounded assumptions against my professional brethren, I do not remember his saying anything of the kind; but if he did say so, he stated what was false. I feel sure that, as a gentleman, he will either repudiate or substantiate the charge. In reply to Mr. Lawson Tait's statement "that the Court of Appeal, in a similar case, decided it exactly opposite to my contention," I can only say that if he will condescend to cite the case to which he alludes I will soon convince him that he mistakes the drift of the decision. The only reply to my arguments, further than this inaccurate statement of law, is a reference to the above insignificant meeting, and to the proxies on either side. With regard to the latter, I discouraged the sending to me of proxies, of which I had a good many offers; while Mr. Lawson Tait issued to those members whom he did not know to be hostile stamped proxy papers printed in his favour. With regard to these, I ask Mr. Lawson Tait whether they were issued at the expense of the Union. I should consider the use of the funds of the Union for such a purpose unjustifiable in the extreme. At the meeting on Jan. 7th Dr. Saundby and others assured me that they would be very glad if a few hundreds would leave the Union, as it was getting inconveniently large, and they did not at all wish it to increase. With such views as these I am hopelessly at variance. The annual meeting of the Union has been in London hitherto. I presume it will be in Birmingham this year. If the opinion of the majority of the Union had been desired, one of the meetings altering the articles would have been called in London. When I know the actual opinion of the Union I shall know whether I can continue to serve on its council and to contribute to its funds.

I am, Sirs, yours faithfully,

Highgate, Jan. 19th, 1892. HUGH WOODS.

THE TREATMENT OF ERYSIPELAS.

To the Editors of THE LANCET.

SIRS,—The recent correspondence in your columns on erysipelas induces me to recall a method of treating this disease, invented in the pre-microbic era 1874-5, when antiseptic surgery was only practised in out-of-the-way places and the phagocyte unknown. The method simply consists in applying constriction, in some suitable way, above or beyond the rash. The original paper, a thesis for the M.B. Cantab. 1875, was deposited in the defunct *Medical Times and Gazette* on April 18th, 1885, and I now resuscitate it partly because I think the results obtained by the treatment advocated therein deserve to be more widely known, but partly also because I am curious to learn how extreme phagocytists would explain results obtained by merely mechanical means.

I am, Sirs, yours truly,

Suffolk-street, S.W., Jan. 16th, 1892. R. G. HEBB.

LITERARY INTELLIGENCE.—Messrs. Cassell and Company have announced the publication in a few days of "The Year-book of Treatment" for 1892.

MEDICAL FOLK LORE IN THE HIGHLANDS OF SCOTLAND.

(FROM A CORRESPONDENT.)

THE student in any branch of knowledge has always open two main sources of information: on the one hand current Science, on the other popular Lore. The first gives him, in definite compass, by recognised authority, certain accepted views tinged always by the general interpretations of the time. The second, if he extend to it his inquiries, he will find to be a vast repository of bygone views and interpretations. The shades of former orthodoxies, ideas long dead to latter-day science, here actually survive in our midst, embodied in numberless proverbs, beliefs, and observances. Of this vast mass of folk lore, and especially of that which relates to Medicine, it is obvious that the essential part is a collection of *acts* and not words. It is essentially an embodiment of custom and usage, and is constantly fluctuating and altering in character. One may regard it at any time as the last term of a long series stretching back since folk began, and yet, with all its antiquity, continually subject to additions and subtractions. Many old cures die out for want of support in the popular mind, whilst on the other hand no great lapse of time is required to remove a new idea, and the practices founded upon it, from its favoured place in the medical mind to the traditions of the people. The springs of science constantly follow that course, taking up the characters of the strata through which they percolate, and, issuing in mingled forms, supply, if not the genesis, at least the constant replenishment of popular knowledge and practice.

The most cursory examination of medical folk lore reveals an infinite variety of means and modes of cure, many no doubt of great antiquity. The following examples are taken from one limited district of the Highlands. It is not easy in some instances to form any opinion of their origin, but for the most part they fall naturally into a few groups, according to the main principle or ruling idea on which they seem to be founded.

1. Beginning with the most rational of these principles, there is first a very large group of practices resting on a basis of empiricism or experience. This much-abused principle grows in dignity when it is remembered that experience, however rude, passes by insensible degrees into the scientific method of precise experiment, on which modern medicine endeavours with more or less success to establish its practice. For examples of this most rational group: Some recommend that in whooping-cough the child should be taken across a ferry; others that he should above all go to live in another property; others that he should go to a house where master and mistress have possessed the same surname. All these procedures involve change of air, which has in such cases no doubt been found beneficial. On the same general principle, colt's-foot is used in asthma, warts are washed in pig's blood, and a person with weak lungs takes with great advantage a preparation of twenty-four different herbs, which occupied several weeks to collect. "Holy wells" come under the same class of remedies, for, in the first place, they are esteemed "holy" because curative, and only subsequently curative because "holy." With respect to the treatment of sprains, the very diverse and prevalent practices used under the name of "bone-setting" clearly come under this head; but another, and in this district equally common, mode of treating sprains is to tie a piece of red thread (some prefer white) around the injured part. The curative virtue of the thread or "strivan" is implicitly believed in. Considerable force is often used in applying it, and sometimes it seems to exercise a certain amount of support; so that probably this practice also, like manipulation, rests on an experiential basis.

2. The second principle, *similia similibus curentur*, underlies many popular curative practices of great antiquity, and is still frequently illustrated in contemporary medical lore. Common erysipelas (called by the Highlanders "the rose") is a case in point. "The doctors is verra ready," said one old patient, "but they've no sense wi' the rose." She went

Digitized by Google

on to say that a bit of red cloth certainly prevents the return of the malady. "I wear a bit scarlet comin' doon ower mi' head for that verra purpose itsel' every day o' the year." An infusion of adders' heads is used as a dressing in snakebite, and, it is said, with excellent results. Another supposed remedy of a somewhat extraordinary character appears to rest on the same principle. It is for epilepsy ("falling sickness"); and in two cases known to the writer has been actually put in practice in recent years. This is no other than the scrapings of the inside of the skull of a man recently dead, in the one case of epilepsy, and in the other by suicide. The directions are to "scrab it wi' a knife, and tak' it in water, as much as a pooder o't." In the second case the patient himself, a man from the far north, procured the necessary material by exhuming the body of the suicide at night.

3. We come now, in the third place, to a large group of practices based on the principle of substitution or imagery, and on the seductive habit of reasoning from imagery. This principle has not been without an influence on medical opinion, and is probably the ancestor of the doctrine of *similia similibus*. It underlies the customs and beliefs of pre-scientific men to an astonishing extent. It is exhibited in numberless rites, from propitiatory offerings and sacrifices downwards; and it is important to observe that all early ideas of imagery, even in practices affecting the human body, imply the exercise of what we call "supernatural" power. There is therefore in all cures coming under this head a belief, generally ill defined and sometimes unconscious, in the coöperation of unseen powers. For warts a small piece of meat (some prefer three knots from a stalk of barley) is buried with certain formalities. As the meat decays the warts disappear. For epilepsy a famous cure is to bury a black cock alive, if possible at the spot where the first fit occurred. This is clearly propitiatory, and is paralleled by closely similar rites among different tribes. Of this barbarous proceeding the writer is now aware of six modern instances. One of the latest was accompanied by the prayers of an esteemed elder, who is said to have attended the ceremony for the purpose. Some say that it is necessary to inter with the cock some of the patient's hair and nail parings, and, according to one account, a small bird known as the "cnag" must share the same fate. It is also stated that a black cat would do if the cock were a-wanting; and that the place of burial must never afterwards be disturbed or the complaint would return. *Apropos* of epilepsy, although it is a departure from the order of discussion, one or two curious beliefs may be noted. The epileptic who has fallen into fire or water can never be cured. If a child or even grown person pass between the patient and the fire he will run the risk of taking the disease. Even if a dog or cat passes in the same manner, the animal may carry the disease to a healthy person. One who has been cured may not touch a dead body or even see a funeral without endangering the return of the disease. In the two following incidents, although there was no question of epilepsy, the same curious ideas find a place. An old neighbour lost his "good-father" some years ago after a long illness during which a favourite cat had been much attached to the sick man. The night he died the two sons thought it needful to drown the cat, lest after approaching the remains it should carry evil to others. In the second case the informant relates that her grandfather was in a house where someone had just died. The window was unfortunately left open, and the cat leaped into the room over the dead body. The animal then approached the old man, with the result that he soon after took a severe fit. "They put the cock under him" (!), but all was unavailing.

The most perfect example of practices founded upon imagery and substitution is afforded by the use in witchcraft of *Cuirp Creadh*, or clay bodies. Nearly half a dozen instances have now been met with in this district in which women with malignant purpose have fashioned clay images representing the person to whom they desired ill, and then subjected the work of their hands to slow destruction. Some years ago a fine healthy lad fell sick. Witchcraft was thought of, and suspicion fell on an old woman to whom the young man had behaved disrespectfully. Advice was therefore taken in Inverness of an ancient dame who was generally credited with uncanny powers, and she, without leaving her own door, directed the friends to return home and look behind the house in a certain stream. This they did, and found a clay image partly destroyed by running water. Moreover, to make destruction doubly sure the end of an old sword blade had been driven into its side. They removed the *cuirp creadh* with great care and took it into the house, but the damage had gone too far and the man died. In most of these cases the image has been stuck over with pins, and in one instance the victim complained during his illness, which was fatal, that he had pain as if all the pins in Dingwall were stuck into him. Closely similar practices, even to the minutest detail, are found to be almost world wide.[1] The ruling idea of imagery is illustrated in the rude curative practices of all nations. The Philistines of old sought relief by forming golden images of the tumours that afflicted them, and the physicians among the North American Indians fashion a representation of their patients' disease, and carry it off to the woods and bury it. So in all ages to walk by sight for a little space helps faith on a long journey.

4. There is still another group in which the practices of healing are founded simply and solely on the possession or assumption of supernatural power. It is worthy of note that here the cure is always subject to the observance of certain definite rules. Persons gifted with powers of this kind will not under any circumstances accept payment for their services. Again, some secret words or form of prayer appear to form a necessary part of the method, and this secret the possessor dare not divulge. At the same time he may not die without transmitting it to another, and this other must always be of the opposite sex. Usually the power of any individual is limited to a particular complaint, or group of associated complaints, and there is hence great variety of gifts. The man who killed the cat on the night of his father's death is credited with special powers for stanching the flow of blood. This he does without seeing the sufferer; he has simply to know the name. Another has similar powers in regard to toothache, and a third in affections of the throat or eyes. It is said that nobody in this region would dream of consulting a medical man for rickets. A wise woman is called in and goes through a succession of movements variously described, accompanied by certain words. For sprains, and perhaps for fractures, there likewise seems to be special gift to special persons. These are not to be confounded with ordinary bonesetters, in whom the practice rests, as we have seen, on a different footing. For scrofula (King's evil) there is the great and much-prized instrumentality of the "seventh son," who is regarded in the Highlands as gifted with altogether exceptional powers of healing. The writer has known of three of these individuals. Common water, when drawn and given by such a one, is reckoned an infallible cure for this complaint. Any seventh son will possess the power if certain formalities are observed at his birth, and provided also—and this is a suggestive circumstance—that he has not been convicted of serious sin. A further curious instance of the purely supernatural in a curative practice is the use of "silver water"—water in which silver has been dipped, with certain observances—to remove the effects of the "evil eye." One more example must conclude the series. Not long since a shepherd, from motives of revenge, was laid under the enchantment of a woman. Having been ill two years, and becoming worse, his friends consulted another wise woman. She pitted her power, so to speak, against that of the first, and succeeded, by the use of certain procedures, in breaking the spell and removing the evil! This is certainly an extreme case, in which we have proceedings founded on the idea of one supernatural power counteracting and defeating another; but to these extreme cases there is an easy gradation from the simplest and commonest modes.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Influenza in the North of England and the Borders.

THERE is scarcely anything of note to write about except influenza and its ravages as regards the northern counties, and over the borders it may be said to be everywhere, and almost in every house. A large number are affected at Langholm, including a large percentage of those employed at the woollen mills. Masters and men have been down,

[1] See Sir John Lubbock's History of Civilisation &c.

Digitized by Google

and in many houses all members of the family have been stricken simultaneously. Coming on to Carlisle, it is said to be more widely prevalent than ever. Most of the Church of England clergymen have been already down with it and are on the road to recovery. It is said now that most of the Methodist ministers in the town are also stricken. The places of worship are so poorly attended that it is evident that a great proportion of the inhabitants are afflicted with the scourge. The death-rate of the city of Carlisle has been very high for the past two weeks—nearly double the average. Upon the various large works of the city and in the post-office and other institutions work is severely crippled by the large number of hands on sick leave. At Hexham the medical officer of health, Dr. Jackson, reported that the death-rate of the last quarter of 1891 was equal to 42 per 1000, and was the highest noted since 1875. This high rate was principally due to whooping-cough, measles, and various diseases of the respiratory organs. At Kendal and Wigton influenza is reported to be very bad.

Influenza is prevalent about Middlesbrough, and Dr. Ketchen, one of the oldest practitioners in the town, fell a victim to pneumonia following influenza after a brief illness. Dr. Ketchen was attended by various medical friends, and was also seen by Dr. Eddison of Leeds. Medical men are so low now in their stock of vitality from continued overwork that they stand a poor chance of recovery when attacked with pneumonia. It would be well for them to remember that the strain is very great to their constitutions, and the epidemic exceptional, and they should in the case of large practices secure efficient assistance in time. A horse even cannot be kept running continuously, nor can a medical man go on without rest, food, and sleep. I mention this because many have told me of the large amount of work they are doing just now, often single-handed, or with their ordinary assistance—but at what a cost to health and risk to life!

With regard to the importation of influenza from foreign ports, it was mentioned at the last meeting of the Tees sanitary authority that 179 vessels had been inspected during the past month, and that no case of influenza or infectious disease had been noticed. This, it was mentioned, was contrary to the popular opinion that it was imported by vessels from foreign ports. The outbreak of the disease in isolated dwellings shows, I think, very clearly that it is malarious or atmospheric, and the prevalence of the disease amongst the lower animals supports this view.

Newcastle-on-Tyne, Jan. 21st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Death of H.R.H. the Duke of Clarence.

TO-MORROW (Wednesday) being the funeral day of H.R.H. the Duke of Clarence, the classes will not meet either in the University or in the Extra-mural School of Medicine.

Edinburgh Royal Infirmary.

An adjourned meeting of the contributors to the Royal Infirmary was held on Monday last, to consider the plan, of which an outline has already been given here, for the extension of the infirmary buildings as proposed by the managers. A good deal of discussion took place, and the plans and proposals were objected to, and it was finally agreed that the plans be recommitted to the managers for consideration, their report to be laid before a meeting of contributors to be specially convened to consider them a month hence.

Health of Edinburgh.

The mortality last week was 93, making the death-rate 18 per 1000. Diseases of the chest accounted for 51 deaths, and zymotic diseases for 4. The intimations for the week were typhoid fever 6, diphtheria 5, scarlatina 24, and measles 20.

Examinerships in Edinburgh University.

Of the examinerships which fell to be filled by the University Court the following are among the appointments:—Prof. Stirling to Physiology, Dr. W. Craig to Materia Medica, Dr. A. Bruce to Pathology, and Dr. Beatson to Surgery.

Aberdeen City Hospital.

The sub committee of the Public Health Committee of the Aberdeen Town Council appointed to investigate into certain charges made against the City Hospital, have submitted their report to the Town Council, and conclude that they have every reason to believe that the management of the hospital is thoroughly efficient, and that, as far as possible, every care is exercised for the purpose of seeing that both children and adult patients are kindly and properly treated. The whole of the patients who were examined bore testimony in favour of their kindly treatment in the hospital.

Jan. 19th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Dublin Hospital Sunday Fund.

THE total receipts for the collections in aid of the Dublin Hospital Sunday Fund held last November amounted to £3982 19*s.* 5*d.*, which includes a sum of £66 17*s.*, the proceeds of a match between the Leinster Branch of the Irish Rugby Football Union and the Hospitals' Team. The total shows a falling off of £205 3*s.* 6*d.* as compared with the year previous.

Proposed National Hospital for Consumption for Ireland.

The promoters of the proposed hospital for phthisis point out the necessity for a hospital of the kind in the vicinity of Dublin. During the last few years great advances have been made in the knowledge of this disease; its method of spreading infection has been clearly demonstrated, and its treatment has been much improved. It follows that there is great need of a hospital where phthisis can be properly treated, and which will be both a curative and preventive institution. The malady is a very common and very fatal one in Ireland, accounting for about one-tenth of the deaths from all causes. It is proposed that the scheme shall include the establishment of a hospital for at least 100 beds, which shall be vested in a Board of Trustees appointed by contributors to the building fund. If the scheme is carried it will materially benefit the general hospitals, relieving them of their phthisical cases, the treatment of which, necessarily of a lengthy and costly character, cannot be successfully carried out in such hospitals.

Poor-law Returns for 1891.

By a recent return of the Local Government Board it appears that the total expenditure in 1891 for the poor-law services was £1,407,886, or an increase of £6014 over 1890. The expenditure was under the heads of in-maintenance, out-door relief, expenses under the Medical Charities Act and under the Public Health and Superannuation Acts, &c.

Death of Mr. Zachariah Johnson, A.M., F.R.C.S.I., of Kilkenny.

I referred last week to the serious condition of this gentleman, who at a very advanced age was a sufferer from influenza. I regret to state that his death took place on the 12th inst., at the age of eighty years. Mr. Johnson was surgeon for many years to the County Infirmary.

Cork Poor-law Medical Officers Association.

A meeting of this Association was held on Saturday last to consider what action should be taken in reference to the Bill entitled Medical Charities Amendment Bill, 1892, about to be brought in by the Irish Medical Association. Mr. Keating proposed the following resolution: "That we regard the draft Bill of the Irish Medical Association (entitled Medical Charities Amendment Bill, 1892) as an attempt to delay useful legislation on the subject of poor-law medical reform in Ireland; if such a Bill be introduced into Parliament we pledge ourselves to give it every opposition in our power; and we decline to accept any Bill as a settlement of our claims which does not deal with the questions of pay, pension, and annual holiday." Dr. Sandiford also spoke in opposition to the proposed Bill, and seconded the resolution, which was adopted. The Association now numbers over seventy members.

Barrington Hospital, Limerick.

The efficiency and increasing benefits bestowed by this Charity are well maintained. During the past year 501 patients were received into the hospital (the highest record of intern patients), and 2530 were treated as extern cases in the dispensary. The parts of the house and ground which were formerly held by the City Dispensary have been improved and put in good order. The old dispensary rooms have undergone necessary renovation and cleansing, and, as soon as the furniture has been supplied, will be ready for the reception of private patients.

Union Medical Officers.

At a largely attended meeting of the County Limerick Branch of the Irish Medical Association, Dr. Thomas Hayes (Rathkeale) in the chair, the following resolutions were passed without dissent:—"That union medical officers should be permitted to retire on a pension of two-thirds of salary and emoluments at twenty years, and upon full value at thirty years' service. That the fees for registration and vaccination should be equalised with those obtaining in England and Scotland. That we are unanimously of opinion that the present salaries of Poor-law medical officers are wholly inadequate, and should be increased by 75 per cent."

Jan. 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Influenza in France.

ALTHOUGH Paris itself may be congratulated on being comparatively exempt from thescourge which is playing such sad havoc in different parts of England, other districts of France have not been so fortunate. In the coal-mining department of the Pas-de-Calais quite a fifth of the population is *hors de combat*. At Cherbourg, seventy-three persons succumbed to influenza in the first week of this month, and at Saint-Etienne the mortality has increased 45 per cent. Lille, Roubaix, Tourcoing, and Dunkerque are being severely tried; and at Prades, in the Pyrénées-Orientales, the mean mortality is tripled, in one instance four out of a family of five persons having died. I may mention that in the few mild cases I have been called upon to treat lately in Paris, I have found five-grain doses of phenacetin every four hours answer capitally, the pain ceasing and the temperature being lowered rapidly.

The Length of the Urethra.

To judge by the varying figures given by different authorities, it would seem to be advisable to allow a large margin when asked at an examination to state the length of the male urethra. The *Union Méd. du Nord-Est* publishes a list of measurements gathered from the writings of twenty-one different anatomists, from which it appears that while Richet gives the length as 15 centimetres, Heister allows more than its double—viz, 33·5. Sappey states that the length varies not only in different individuals, but also with age. Richet denies this latter assertion. A definite understanding on this moot point is urgently required, seeing the popularity of Guyon's instillation method of treatment for gleet.

Yet another New Medical Society in Paris.

In last week's correspondence it was announced that an association of foreign doctors practising in Paris had been recently founded, and reference was made to the two-year-old Continental Anglo-American Medical Society. It is felt by English practitioners residing in this city that both the above bodies are open to the same reproach in being somewhat too heterogeneous in the matter of membership, and it is thought that some effort should be made to bring more closely together those British practitioners residing in France who, in addition to being subjects of Her Majesty, are possessed of British diplomas. It is accordingly in contemplation to create an association whose business it shall be to give such information to the public through its published official list as to enable them to distinguish between the real and the pseudo-English physicians, as also to promote good-fellowship between men hailing from the London, Edinburgh, Dublin, and provincial schools of medicine in the old country. I heartily wish the new society the success it deserves.

Breton Ignorance.

M. Renan's compatriots enjoy, rightly or wrongly, the reputation of being rather behindhand in civilisation. A local doctor has just addressed a report to the Préfet of Morbihan, from which it would appear that these primitive people have not been altogether maligned, at least in so far as ignorance of the laws of health are concerned. In 1884 typhoid fever made its appearance in the commune of Langoëlan, whose inhabitants, distributed over numerous hamlets, number 1350. Twenty-three hamlets and the market town have been visited by the scourge, some of them several times in succession since the first outbreak, and typhoid fever has evidently taken up permanent quarters in the unlucky commune. Add to this that the mortality is enormous (at Kervoten seven cases with four deaths, and at Cosquer eight with five deaths), and it will be conceded that the state of affairs is serious. The reason is not far to seek; I give it in Dr. Langlais' own words: "Les déjections sont répandues à la porte, sur le fumier de la cour; au milieu de cette cour est creusé le puits, véritable drain qui pompe tous les liquides et tous les germes. Chaque malade est un objet de curiosité qu'il faut visiter, à qu'il faut serrer la main, qu'on doit embrasser, et l'on boit au même verre que lui." What a happy hunting ground for the lively typhoid bacillus, and what scope for the sanitary reformer!

Paris, Jan. 20th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Influenza.

ACCORDING to official statistics, only 25 persons died in Berlin of influenza between 1878 and 1889. Of these years 1887 had the highest influenza mortality—namely, 7. The number of deaths in 1889 was 54, in 1890 90, and in 1891, before Dec. 12th, 286. Those are all the cases in which influenza was expressly given as the cause of death in the death certificates. In 1890 only June and November had no deaths from influenza; in 1891 only July and September. There were 5 deaths from this cause in the second week of last November, 36 in the next, 61 in the next, 88 in the next, and 80 in the next. The Berlin horses are said to be suffering pretty severely from influenza. Kitasato, who works under Pfeiffer in the scientific department of Koch's institute, has succeeded in cultivating Pfeiffer's influenza bacillus in pure cultures to the tenth generation. In several uncertain cases the diagnosis of influenza has been confirmed by the finding of Pfeiffer's bacillus in the blood.

An Explanation of the Effect of Quinine.

An explanation of the therapeutic effect of quinine in malaria has at last been found. So long ago as 1867 Dr. Karl Binz, professor of pharmacology at Bonn, gave an explanation which was little noticed at the time, but has now been signally confirmed by the discovery of the germ of malaria. He showed that quinine hydrochlorate, with neutral or slightly basic reaction, is a strong poison for the protoplasms of decomposing plants, and greatly hinders many fermenting and putrescent processes. A. Laveran, the discoverer of the plasmodium malariæ, has demonstrated that this organism disappears from the blood of malaria patients after the administering of quinine, and that quinine, if permitted to act upon it directly, kills it.

The Berlin Medical Society.

At the general meeting of the Berlin Medical Society on the 12th inst. Professor Virchow was appointed President by an enormous majority. Of 137 votes, 135 were given for him, one for Professor von Bergmann, and one for Professor von Bardeleben.

New Books.

"Evolution" (a new view of Darwinism), by Wilhelm Russbüldt; "On the threatening Physical Degeneration of civilised Mankind and the Nationalisation of the Medical Profession," by Dr. Schallmayer; "The Tasks and Aims of Hygiene," by Dr. Krocker; "On the Sanitation of Heligoland in the years 1886–1889," by Dr. Lindemann; "On the recently proposed Measures of Sanitary Police for

preventing the Spread of Tuberculosis," by Dr. Behrens; "The Prevention of Mortality in Childbed and of Several Diseases of Women," by Dr. Eberhart (second edition); "How can we Preserve Ourselves and our Children from Nervous Diseases?" by Professor Seeligmüller (second edition); "Take Care of the Health of School Children" (Berlin: Wilhelm Issleil); "Protection against Diphtheria," by Dr. Panse; "The Diseases of the Hair," by Dr. Pohl-Pincus (fourth edition); "Ex Malis Minima": reflections on prostitution, by a University Teacher; "The Riddle of Hypnotism and its Solution," by Dr. Jordan; and "The Fundamental Features of Natural Medicine," by Dr. Sturm (second edition).

Notes on Appointments, &c.

One of Professor von Bardeleben's Christmas presents which came from the Berlin Medical Society was an artistically adorned address of congratulation on the recent attainment of the fiftieth anniversary of his graduation as doctor of medicine.—Professor Klebs of Zurich has resigned his professorship in order to devote himself to private study. His successor is Professor Ribbert of Bonn.—Professor Biermer of Breslau, one of the most eminent clinical teachers in Germany, has resigned his professorship, and will be succeeded by Professor Kast, head physician of the large new hospital in Hamburg, to whom, along with the chemist Baumann, we owe sulphonal.—Dr. Ferdinand Hueppe of Prague, one of the oldest and most eminent of Robert Koch's pupils, has been appointed Ordinary Professor.—Dr. Hermann Reinhard, Privy Medical Counsellor and President of the Medical Board of Saxony, died on the 10th inst. at Dresden. — Professor Knauff of Heidelberg has been appointed Ordinary Professor of Hygiene and Forensic Medicine there.—Dr. Rosegarten, Private Lecturer on Otiatrics in the University of Kiel, has been appointed Extraordinary Professor there.—Dr. von Starck, Assistant in the Medical Policlinic in Kiel, has been appointed Prof. Elessen's successor in that institution, and Extraordinary Professor.—Dr. Erich Peiper, private lecturer in the University of Greifswald, has been appointed Extraordinary Professor in the Medical Faculty there.—Dr. Reinhold Schmaltz, lecturer on histology and embryology in the Veterinary Academy here, has been appointed Professor.

Berlin, Jan. 18th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Death of his Highness the Khedive.

So many stories have been circulated about the illness of the Khedive, which ended so suddenly and so disastrously, that it may be well to give the true account as gleaned from eye witnesses. It appears that the Khedive gave a dinner on Dec. 29th to Prince Damrong of Siam, who was then here, and that this was followed by a visit to the opera, after which his Highness, contrary to his usual custom, returned to Helouan, a desert suburb some three-quarters of an hour by train from Cairo. On Dec. 30th he was tired, but came to his Cairo palace as usual. On Dec. 31st he evidently had influenza, but nothing was known of this until a few days later, when a bulletin was published to the effect that his Highness was confined to his room with a severe cold, and that his temperature was 98°. His illness was considered by everyone to be very trifling until the night of Jan. 6th, when the patient complained of severe pain, for which one of his two Egyptian medical attendants injected morphia. As there was no relief he twice repeated the injection, giving four-fifths of a grain within about twenty minutes. The doctor then went to bed himself, but was roused later by the servants, who were frightened at the Khedive's state. This doctor then told the Vice-Reine there ought to be a consultation that night, but his colleague tried to oppose this, and said he took all the responsibility of the illness upon himself. The Vice-Reine, however, sent a special train to Cairo to summon Dr. Hess (Swiss) and Dr. Comanos (Greek), a translation of whose report is subjoined below. When they reached the Royal patient they found him almost dying, with two servants rubbing his legs and a native doctor rubbing his back. They at once ordered brandy or champagne, but none could be found in the palace. They seem to have been somewhat misled by their native colleagues, who stated that they had examined the urine and found it free from albumen, the real truth being (it is said) that there was already suppression of urine, and no analysis of it had been made. The two European doctors would seem to have hardly appreciated the gravity of the situation, for they returned to Cairo for some hours and paid a second visit about noon. They were then compelled to eject ether and caffeine, the drugs being obtained from a good German chemist in Helouan. I may here say that no one seems to have had any confidence during the illness in two Egyptian dispensers who were attached to the palace. The European doctors determined to obtain a specimen of urine by catheter, and sent a special messenger to Cairo for an instrument. One of them, however, in the meantime discovered some catheters at the house of a European colleague resident at Helouan, who refused to lend them, but was quite willing to bring them to the bedside of the dying Khedive. The urine when drawn off was examined by the German chemist, who found some blood from the catheterisation, and about one-twelfth albumen. The specific gravity of the urine was not taken, and there was no microscopical examination. All this time the two native doctors continued to affirm that the patient was better, and could hardly be made to believe the existence of albumen. Telegrams to Cairo continued to ignore the dangerous state of the patient, and nearly everyone was thereby deceived. When his Highness was moribund Drs. Wildt, (German), Ambrosa (Italian), and Binet (Swiss) arrived from Cairo, but could of course do nothing. Death took place at 7.15 P.M. on Jan. 7th, and the death certificate was worded, "Uræmia and pneumonia consequent on influenza." Needless to say the native doctors completely lost their heads before the fatal result, and one of them disappeared entirely for a few days. There was no necropsy, but an examining commission is now being held, consisting of five—Drs. Rogers (English), Ibrahim Pacha and Daruy Bey (Egyptians), Wildt (German), and Binet (Swiss). This may possibly satisfy the international proclivities of certain people in Cairo, but can be of no other use. It is unnecessary here to give the names of the two native doctors. They are two of the five Egyptian doctors who have been raised to the rank of pacha, and, besides having held such appointments as Chief of the Sanitary Department and Director of the Medical School, it should be stated that they owe all their advancement to the family of the poor Khedive whose life they did so little to save. There is now no means of knowing whether the albuminuria was a recent result of influenza or the evidence of chronic but undiscovered kidney disease. All accounts from the palace show the most culpable negligence and ignorance on the part of the native medical attendants. The following is the report of Drs. Hess and Comanos, addressed to the President of the Council of Ministers:—"At your Excellency's request to state our opinion on the illness and death of his Highness the Khedive, we have the honour to submit. On Thursday, Jan. 4th, at 4 A.M., we were called by special train to Helouan to consult about his Highness. We arrived there at 5.30, and were received by the private doctor of his Highness, who in a few words stated that his Highness had been ill for a week with influenza, with no abnormal symptom until the preceding evening, when the fever had increased. His Highness could not sleep, and there was dyspnœa, together with a pain in the left side. That an injection of morphia had been given to assuage the pain. After this statement we entered the sick room, and were disconcerted to see his Highness in a very alarming state. His general state was much altered, his complexion pale, and his appearance haggard. He was held up, half-sitting, in bed by two servants, and he had evident dyspnœa. He was not completely conscious of what was going on around him, and complained specially of not being able to see the light. We found a temperature of 104°, and a pulse too fast, very weak, and easily compressible. On examining the body we found a considerable broncho-pneumonia on the left side and general bronchial catarrh of the right lung. This condition of lungs, although serious, did not, however, account for the cerebral symptoms which were present, and therefore we directed our attention to other organs, and specially to the state of the kidneys. We thereupon asked for information from the doctors in charge about the urine, but we were told that there was nothing wrong. The examination being then

Digitized by Google

over, we prescribed a very rigorous treatment appropriate to our diagnosis, and we left for Cairo to warn important people about the serious state of his Highness. We returned to Helouan at 1 P.M., and were much distressed to find that his Highness's state was decidedly worse, and that not only the chest symptoms were aggravated, but also the cerebral symptoms had reached a hopeless pitch. This last phase showed us clearly the existence of uræmia, and we insisted on seeing the urine, when we were told that his Highness had not urinated since the preceding evening. Then we passed a catheter, and obtained a certain quantity of dark-brown urine which by chemical analysis contained much albumen. We were then quite certain of the nature of the illness, that his Highness, as a sequence of influenza, had been attacked by infectious pneumonia complicated by nephritis of the same kind, and that, in his then state, all hope had disappeared. This did not prevent us from applying the most useful and most rigorous means that science could place at our disposal, but alas! without the least success. And we had the profound regret," &c.

Cairo, Jan. 12th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Influenza Epidemic.

THE influenza epidemic, which reached these shores early in the year and lighted up afresh towards midwinter, has now almost died out. This year the sickness has been more protean in its aspect, more widely spread, and more fatal in its course than the epidemic of last year. The principal manifestation has been pulmonary, and this has also been of the most fatal form. There has been a large number of deaths among the aged, the weak-lunged, and the alcoholics; but in proportion to the numbers attacked the death-rate has not been high Statistics to elucidate this latter point are very difficult to arrange, and are most probably very unreliable, for during the course of the epidemic every ache and pain and slight depression has been diagnosed as influenza.

The Medical Profession and the Political Situation.

The defeat of Sir Henry Parkes and the advent of a Protection Ministry to office in New South Wales is of more than passing interest to the medical profession. Heavy duties have been imposed on drugs, spirituous compounds and medicaments, surgical instruments and dressings. These duties will have the effect of raising the price of medicine very considerably; but I doubt if there are many, even amongst the most ardent of the Government supporters, who will pay their doctors a larger fee. But the duties will also have a beneficial effect in keeping out of the country the very inferior class of goods with which it has recently been flooded. The Ministry, however, have given the profession a *quid* for this increased taxation. They have introduced as a Government measure, and passed through the Legislative Council, a Bill which provides that everyone practising medicine must plainly state in his advertisement or on his doorplate his qualifications for so practising. This is a very small advance towards the regulation of the practice of physic, but it is a step in the right direction. Another good action on the part of the Government was to begin the completion of the Sydney Hospital. There is, perhaps, not a greater monument of political ineptness in all Australia than the Sydney Hospital. Half a score of years ago a new hospital was projected, specifications prepared, the work sanctioned, the money voted, and the contract signed. The old building was pulled down and a temporary structure erected, and the work of the new hospital progressed. Then it was found that the money voted would scarcely pay for the foundations, and that, instead of £60,000 or £70,000, it would require nearly £250,000 to carry out the plans. Accordingly the work was stopped, and the unfinished building has since been an eyesore to the citizens of Sydney. The temporary buildings have not provided the accommodation required, and overcrowding has occurred to such an extent that the chief of the Sydney Fire Brigade made a report on the matter, in which he stated that in the event of a fire breaking out there would be 200 lives lost. Recently a commission was appointed to consider the matter, but the late Government made no move. The medical superintendent, Dr. Hull, has, however, kept pegging away, and made the public acquainted with the dangerous position of the patients, and as a consequence the hospital will shortly be recommenced. Meantime the patients have been reduced in number as much as possible, and have been located in the old nursing quarters, while the nurses have been housed some distance off. Dr. Hull is to be congratulated on the success of his persevering efforts.

Obituary.

BRIGADE SURG. F. R. WILSON, M.B.DUB., L.R.C.S.I.

WE regret to have to record the death of Dr. F. R. Wilson, Brigade Surgeon, 42nd District. Dr. Wilson was educated at Trinity College, Dublin, where he took his M.B. degree in 1857. He entered the army, after acting as travelling physician to the late Lord Bangor, and served in the 20th Regiment for a long term of years. During the Ashantee war Dr. Wilson had charge of the base hospital at Conderis, and for his services in that war was specially thanked by the Director-General and twice publicly thanked by the military authorities. Dr. Wilson served twice in India, and eventually was in 1881 appointed Brigade Surgeon to the 42nd Regimental District at Perth. There he served until he was seized with influenza and pneumonia, from which he died after a brief illness on Jan. 10th. He was much beloved by his brother officers as well as by the men attached to the depôt, and his presence will be much missed by the medical men of the district.

W. WAYLAND KERSHAW, M.D. ST. AND, F.R.C.S. ENG.

A VERY beautiful character suddenly passed away at Surbiton on the 15th inst. The hand of death has recently pressed heavily everywhere, and to the great sorrow of very many friends and patients it has fallen on one of the most honourable and devoted servants of the medical profession. For forty years Dr. Kershaw had practised in Kingston-on-Thames, Surbiton, and the neighbourhood, and with that uprightness of character and professional skill which secured for him a reputation second to none in the county, and, what is perhaps even more, he was esteemed and loved by everyone who had the privilege of his acquaintance, from the highest to the lowest.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on the 13th inst.:—

Anatomy and Physiology.—Charles H. Dunstan, George S. J. Boyd, and Leonard L. Burton, students of London Hospital; James J. Coleman and Herbert E. Cock, of Guy's Hospital; Arthur Stanley and Joseph Ashton, of St. Mary's Hospital; Graham S. Pownall, of St. Bartholomew's Hospital; David H. Fraser, of St. Thomas's Hospital; and John C. Clemesha and Robert A. Bowie, of McGill University, Montreal.

Anatomy only.—Nugent B. Baker, of St. Bartholomew's Hospital; Alfred Carruthers and Walter J. O. Ray, of St. Thomas's Hospital; Percy James Curtis, of Guy's Hospital; Alfred K. M. Curtis and Roderick Sim, of Middlesex Hospital; Arthur A. Lewin, of McGill University, Montreal; and Arthur R. S. Freeland, of London Hospital.

Physiology only.—William G. Noble, of London Hospital; Bernard P. O'Neill, of Guy's Hospital; Frederick A. W. Quay, of Trinity College, Toronto; and Henry C. Clark, of Middlesex Hospital.

Passed on the 14th inst.:—

Anatomy and Physiology.—Walter H. Bracewell, of Melbourne University; Richard Lawson, of St. Thomas's Hospital; Ernest F. G. Tucker, John D. Galloway, and Henry W. Grattan, of London Hospital; Edward W. de Kretser, of Ceylon Medical College; Robert C. Griffith, of Toronto University; Leonard W. Oliver, of St. Mary's Hospital.

Anatomy only.—Wm. C. F. Hayward and Frederick A. L. Hammond, of Charing-cross Hospital; Walter Mawer, Herbert W. Carson, and

Digitized by Google

Mark Taylor, of St. Bartholomew's Hospital; Charles H. Wilmer, of St. Bartholomew's Hospital and Mr. Cooke's School of Anatomy and Physiology; Debonnaire F. Maunsell, of St. Thomas's Hospital; Francis E. Bromley, W. V. P. Teague, and Sidney H. L. Archer, of London Hospital; Frank Romer, of St. George's Hospital and Mr. Cooke's School of Anatomy and Physiology; Gerald S. S. Marshall, of Middlesex Hospital; Edward G. Frederick, of King's College; and William H. Chute, of Westminster Hospital

Physiology only.—Percy L. Moore, of Cambridge University; George M. Bennett, Leonard A. Williams, and Edward D. J. O'Malley, of Middlesex Hospital; Archibald W. Lamb and James E. Jones, of St. Bartholomew's Hospital; Richard Slocock, Vyner Graham, Arthur D. Cowburn, and Savignac B. Stedman, of St. Thomas's Hospital; Joseph A. W. Pereira, of Bombay and Charing-cross Hospital; Walter L. Roberts and John N. Hall, of St. Mary's Hospital; David Evans, of University College; John Heard, of Westminster Hospital; Lewin Bensted and Frank H. L. Cloud, of Guy's Hospital.

In Anatomy and Physiology 106 candidates presented themselves for examination, of whom 32 were referred in both subjects for three months and 4 for six months; 12 were referred in Anatomy only, and 19 in Physiology only. In Anatomy only there were 27 candidates, of whom 5 were referred for three months; 37 candidates presented themselves in Physiology only, 12 of whom were referred for three months.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 15th inst. the following degrees were conferred:—

Bachelors of Medicine and Bachelors of Surgery.—William Henry Fisher, Gonville and Caius; George Pinder, Queen's; and Robert Redman Law, Christ's.

THE HOSPITAL SUNDAY FUND has received an anonymous donation of £500.

HOSPITALS FOR INFECTIOUS DISEASES.—At a recent meeting of the Stratford-on-Avon rural sanitary authority a resolution was carried to provide two or three cottage hospitals in the district for the isolation of patients suffering from infectious disease, instead of having a central sanatorium in the town. A committee was appointed to make the necessary arrangements.—At a meeting of the Mexborough Local Board a letter was read from the agent of Mr. Montagu, of Ingmanthorpe Hall, in which that gentleman consented to give an acre of land suitable for the erection thereon of a hospital for infectious disease.—The Thornhill District Committee of the Dumfries County Council have recommended the erection of two hospitals for infectious diseases—one near Sanquhar, the other at the lower end of the district.—The new hospital for infectious diseases, erected by the Brentford Local Board from designs of Mr. J. H. Strachan, was opened at Ealing on the 14th inst

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

We cannot undertake to return MSS. not used.

THE INFLUENZA EPIDEMIC.

To the Editors of THE LANCET.

SIRS,—In as few words as possible allow me to state that in the later cases of influenza which have come under my care I have found the use of benzole surprisingly beneficial. It relieves the pain in back and head in a few hours, and reduces the fever permanently within twelve hours. *Ex. gr.*: Jan. 10th, 3 P.M. Young woman. Temperature 103°

Digitized by Google

eyes suffused; skin dry and burning; quick pulse; flushed face; pains all over body, &c. Prescribed as follows:—℞ Benzole pur., ♏ 80; spt. vini, ʒ ij.; spt. chlorof., ʒ iiss.; mucilag. trag., q. s.; aq. ad ʒ viij. M. ft. Bis horis ex aq. The first dose gave relief to pain &c. The second dose reduced the heat of the body &c. On Jan. 11th the temperature was subnormal both morning and evening. Patient free from pain; conjunctivæ normal. In fact, the patient was well but for a very slightly accelerated pulse. In view of the want of any known remedy of proved efficacy, benzole is certainly worthy of further trial. If we are to suppose that the influenza germ rests first on the pulmonary mucosa, then, so far as we know, benzole is perhaps the most suitable remedy. Within an hour of its administration the odour of the gas is pronounced in the breath.—I am, Sirs, yours faithfully,

Newcastle-on-Tyne, January, 1892. WM. ROBERTSON, M.D.

To the Editors of THE LANCET.

SIRS,—The recrudescence of the influenza epidemic again attracting our attention in the metropolis, where it is especially virulent in the presence of overcrowding, I should like to bring before the notice of the profession a simple but efficacious prophylactic—a remedy so simple and inexpensive as to be within the reach of every household and of every class of the community. During the two former outbreaks of the influenza epidemic in Westminster I have found it of such service, both in my own house and in my practice, that I now venture to advocate its general use.

I order an iron shovel to be heated in a fire, and have about half a teaspoonful of crude carbolic acid poured on the nearly red-hot shovel, and a dense vapour arises. If a house be thoroughly fumigated daily in this way, special attention being given to the sleeping apartments, I believe the infectious germs of the disease are destroyed, or counteracted, or eliminated. From practical experience I advocate the use of carbolic acid fumes as a preventive of influenza, and also as part of the remedial treatment. When, however, pulmonary complications arise, the fumes must be used with caution.

At this time, when Dr. Richard Pfeiffer has discovered the bacillus of influenza, I should like to hear what effects he finds carbolic acid has on it.

I am, Sirs, yours faithfully,

Westminster, Jan. 9th, 1892. JAMES E. SINCLAIR.

Purchaser.—1. The question is one that had better be referred to a medical agent. 2. The reply to this question must depend upon the date when the purchase is fixed to take effect.

Inquirens.—We are not in a position to give a reply to the question.

AN AID TO DEFECATION.

To the Editors of THE LANCET.

SIRS,—An even greater "aid to defecation" than "pressure on the posterior half of the perineum," which Mr. Heath recommends, will be found in pressure with the finger upon the buttock just externally to the right lip of the anal orifice. Although the rectum in quite the last part of its course passes downwards in the middle line, yet the course of the gut has before that for long been from the left. The main impact of its protrusive force is therefore exercised, by means of the advancing fæcal mass, upon the right rectal wall near the anal orifice. Here therefore the opposing force should be brought to bear. *Experto credo.*

I am, Sirs, yours faithfully,

Tulse-hill, January, 1892. A. B. STEVENS, M.B. Oxon.

FUNERALS IN INCLEMENT WEATHER.

To the Editors of THE LANCET.

SIRS,—Kindly permit me to state that in a leaflet issued by the Council of the Funeral Reform Association, and approved by the archbishops and bishops, occurs the following pregnant sentence:—"Mourners are not expected to do anything, or leave anything undone, imperilling their own bodily welfare, or that of the community." The Association is of opinion that respect is best shown to the dead by due concern for the living.

I am, Sirs, yours obediently,

F. LAWRENCE,
Hon. Sec., Funeral Reform Association.

Westow, York, Jan. 18th, 1892.

Viator.—Several articles on the respective merits of different health resorts have appeared in THE LANCET, to which we must refer our correspondent.

Ubique has forgotten to enclose his card.

THERAPEUTIC VALUE OF TURPENTINE.

To the Editors of THE LANCET.

SIRS,—I can fully corroborate what Dr. Chapman says as to the therapeutical value of turpentine. During my period of service in the Royal Naval Hospital at Jamaica a large number of cases of typhoid fever came under my observation, the treatment I invariably adopted, in fact the only medicine I almost ever found it necessary to give, was turpentine in six-minim doses. Made into an emulsion with mucilage, the results were eminently satisfactory.

I am, Sirs, yours faithfully,

W. J. EAMES, M.R.C.P.I., &c.
Inspector General, Royal Navy.

Harleyden-road, N.W., Dec. 2nd, 1891.

NEWSPAPER ADVERTISEMENT OF MEDICAL SUCCESS.

A CORRESPONDENT in Liverpool sends us a paragraph from a newspaper referring to recent statements in THE LANCET as to the comparative non-success of means for disinfecting the typhoid poison or the diseased portion of the bowel and the greater success of a Liverpool practitioner described in our own columns. We may safely assume that the practitioner in question was no party to the publication of the paragraph in question. Clearly, newspapers are very wrong media for such paragraphs, which are likely to mislead the public.

Scrutator.—Our correspondent does not very clearly indicate which of two letters he refers to. But we cannot say that either strikes us as exceeding the bounds of what is permitted in a contest. Candidature has to be justified, and a candidate can scarcely do less than give the history of his professional career.

Mr. J. W. Greenwood.—Probably the gift could be obtained by application to Sir Henry Ponsonby.

Dr. Pisani.—We know of no such establishment.

"KISSING THE BOOK."

To the Editors of THE LANCET.

SIRS,—Permit me to point out that the very reasonable objection entertained by many to kissing the greasy cover of the Bible placed in their hands when the oath is administered in the usual form in the police courts and courts of justice is met and provided for by Clause 5 of the Oaths Act, 1888, Chapter 46, which runs as follows: "If any person to whom an oath is administered desires to swear with uplifted hand, in the form and manner in which an oath is usually administered in Scotland, he shall be permitted so to do, and the oath shall be administered to him in such form and manner without further question."

I am, Sirs, yours faithfully,

Jan. 19th, 1892. L.

Mr. Wm. Mackenzie.—It is perhaps needless to say that the quotation in the announcement is unwarranted.

Student should consult our Students' Number, wherein will be found all the information he desires.

Indomitable should consult a physician. We do not give advice.

ACUTE GOUT.

To the Editors of THE LANCET.

SIRS,—I beg to inform you that I have in three consecutive cases of acute gout found the blood to be swarming with a long encapsuled bacillus, side by side with which numerous crystals of biurate of soda are to be seen. I should be much obliged if you will kindly place this observation on record, to establish my claim to priority in the matter. I trust, however, to be able to give you some further description of this hitherto unrecorded bacillus in a future communication.

I am, Sirs, yours faithfully,

Putney, S.W., January, 1892. EDWD. GRÜN.

Leverton.—We have already expressed our opinion. (See THE LANCET of Jan. 7th 1888, and May, 1889.

J. G. F.—We believe there is no warrant for the assumption, but the question has not been exhausted.

THE HODGSON FUND.

To the Editors of THE LANCET.

SIRS,—Allow me to acknowledge the following amounts for the widow and children of the late Dr. W. Bacon Hodgson:—Amount previously acknowledged, £62 12*s.*; British Medical Benevolent Fund, £18. Total, £80 12*s.* As this fund will now be closed, any further contributions will be gratefully received.

I am, Sirs, yours faithfully,

J. PHILLIP TOPPING.

271, Romford-road, Forest-gate, Jan. 18th, 1892.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—In the report of my second case at the Medical Society (THE LANCET, Jan. 16th, p. 141, line 4 in second paragraph of first column, or twentieth line from bottom of page) "right" should be *left*. The superficial gumma is, of course, on the same side as the paralysis. Readers will doubtless perceive that the error is clerical; but I should be obliged if this correction be inserted.

Believe me, Sirs, yours very truly,

Leeds, Jan. 18th, 1892. T. CHURTON.

THE BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of THE LANCET.

SIRS,—At the annual meeting of subscribers yesterday a vote of thanks for the great assistance given by you to the fund by permitting the insertion of appeals &c. was passed, and I was requested to inform you of the fact.

I am, Sirs, yours truly,

Jan. 15th, 1892. EDWARD EAST, Hon. Sec

The Harveian Lectures
ON
COMMON NEUROSES, OR THE NEUROTIC ELEMENT IN DISEASE AND ITS RATIONAL TREATMENT.

Delivered before the Harveian Society of London, Nov. 19th and 26th and Dec. 2nd, 1891.

BY JAMES F. GOODHART, M.D., F.R.C.P.,
PHYSICIAN TO GUY'S HOSPITAL.

LECTURE II. (*Concluded.*)

WHEN we come to consider the case for adults I cannot say I am so hopeful, and one of the best evidences of its intractability is to be found in the number of patent medicines that abound for the cure of asthma. The diseases of children would not keep a quack in bread and cheese for a fortnight. The adults are the patronisers of the various cures for asthma, and who carry Himrod in their pockets and call it a cure, when all the while there never was, and never will be, a better illustration of the toils of the quack; for with each fresh whiff the sufferer is dragged deeper into the abyss of chronic asthma. This is what they come to. I will take my last case, a young lady aged nineteen. Her mother had suffered much from hay fever, and *her* mother had had asthma. She had been an asthmatic since the age of eleven, and she had indicated her neurotic inheritance at a much earlier date by never having been able to eat egg in any form or combination. She sneezes much and suffers much from catarrh. She is now hardly ever free from asthma, but it is worse at night, and she burns Himrod three or four times every night, by which means she gets a fair amount of sleep, although her nights are very disturbed and she is unable to lie down much. Here was the note that her medical man sent with her. "She has suffered almost from infancy from spasmodic asthma. She has taken everything in the legitimate pharmacopœia, and tried with varying success Hare's, and Himrod's, and twenty other quack remedies, besides other nostrums for smoking. She is a frail, weakly-looking girl, but she has admirable courage and spirits, notwithstanding the years of suffering through which she has struggled. She is, as I am, not over-sanguine as to permanent relief." And who could do otherwise than endorse this doleful view? Here was a young lady with years of a baneful habit upon her, a very different thing from a child affected with the same disease; almost the same difference as between the child in its first convulsion and the confirmed epileptic of twenty years or more. To offer her drugs under such circumstances, or rather drugs alone, as the panacea might well seem a mockery, and I began at the other end. I explained to her that the temporary ease that she undoubtedly procured from Himrod's cure—and this remedy is certainly one of the most successful in procuring temporary ease from the distress of the paroxysm—was dearly purchased, and that each release so obtained let her more deeply into the slough of despond. She had got into a bad habit that needed to be broken, and that in the attempt to break it she would at this time of the day of her disease realise to the full the meaning of the words "through much tribulation ye shall enter the kingdom of heaven." If ever there was a heaven to be begun on earth it was to be found for this poor child in the relief of her now constant suffering.

It has not been my purpose in preparing these lectures to deal in any way with the details of treatment by drugs; for there are those here at whose feet I would rather sit in such matters. I have rather aimed at dealing in a comprehensive spirit with the principles that underlie these diseases, and which ought to, and must eventually, energise all our treatment. But lest it should be thought that taking the patient back to, or rather putting her perhaps for the first time in her life face to face with, the problem that she and I had both to deal with—and as I think she far more than I—I was giving her a stone when she came for bread, let me say that I did not send her altogether empty away; but that I believe most firmly in the free administration even in these old cases, and at all times of life at which it occurs, of iodide of potassium and the ethereal tincture of lobelia, for the relief of the asthmatic condition, and that I feel certain that arsenic taken also in free doses, and with breaks, over a long period of time—several months—is a great help by its action on the nervous centres in preventing the recurrence of the paroxysm. I am no friend of the as-he-was and as-he-is description of the results of treatment, but it so happens that a few days ago this young lady, without any asking on my part, thought fit to write this note to me: "I am writing to tell you how very much better I am. I can lie down at nights; I have no asthma after eating; and I never have to burn anything or smoke. In fact, I have hardly had any asthma for the last two months, and the slight returns of it have gone off after one dose of the medicine."

Before I have quite done with asthma let me return again to Himrod and drugs of that ilk. I have made a serious charge against them, and I do not doubt for a moment that there are those here who will abundantly confirm all that I have said. But I want to say more—viz., not only do they confirm this disease of habit; but they do more, for in the long run their repeated use leads to enfeeblement of the heart muscle, and to its dilatation; and thus they introduce serious, and often fatal, complications. Mind, I do not say they must *never* be used—I have seen too much of the distress of bad asthma to say that; but I do say, as I have heard it said of the doctor's brougham, that it is the first nail in his coffin, that when an asthmatic takes regularly to such remedies as these, they are equal to a good many coffin nails.

I come now to the last group on my list for to-night—the neurotic conditions that involve the circulatory system,—and perhaps chief of these is angina pectoris; but I will not take that first, because some might be inclined to question the right of this affection to the title of a neurosis, and even if it has that right, as I think it undoubtedly has in some instances, it is still a little off the lines I have hitherto been considering, and there are other neurotic conditions that may well be considered. And first of all I may allude to the common affection the being the conscious possessor of a heart. It always strikes me as the most astonishing thing that a man may have a heart of twenty, thirty, even forty ounces, and yet be unconscious of its pulsations, although to the bystander the heaving of the chest provokes a recognition of the fact obtrusively. But this heart conscience occurs in quite other cases, and verily it is a sprig from the garden of Eden, for it is a genuine knowledge of good and evil, the good of it being there, but veiled from sight. It is good knowledge if only the possessor could believe it, for it mostly tells that there is nothing serious the matter, and it is evil in that it enshrouds the mind of its possessor in spectral fancies of which he is utterly unable to dispossess himself. Yes! Once to know you have a heart in this fashion is to become full of an idea that it is wellnigh impossible to dislodge, and there is no doubt whatever that it takes a good slice out of the happiness of very many lives. And now comes the point. There are many refuges for the destitute of diagnosis in medicine. A delicate spine is one, a delicate chest another, a torpid liver another, consumption of the bowels another, gout another, neurotic—yes! I will not leave that out—another. We cannot do without them, but there are some that are much more two-edged than others. I do not so much mind a man being told he has a torpid liver, if the doctor does not know what is the matter with him, because the liver is a benevolent deity, and we lay our pills at its shrine without any violent explosion either way, and the public have learned to recognise this. But "delicate lungs" or "a weak heart," which run up a sword over the head of the victim with sudden death, or consumption engraved thereon, when there is nothing serious the matter, and often because we are unconsciously looking after our own reputation, and are afraid of making a mistake which someone else may catch us up in, is not a trifling detail, for a weak heart to the public is as precise a diagnosis as it is vague and unmeaning to the instructed. To us it means nothing, but there are hundreds of people going about and nursing their hearts because they are weak, but with nothing really the matter, and that idea they must have got by medical consent in most cases. Then I have to say that the term is applied to all sorts of conditions that have nothing in common. For example, a stout lady of sedentary habits comes for some trifling ailment, and she starts with the announcement,

Digitized by Google

"I know I have a weak heart, Dr. So-and-So said so years ago." I examine her heart, and it is, as far as present means of diagnosis go, absolutely healthy. And I have little doubt that Dr. So-and-So, looking at his patient's physique, and judging her rightly of corpulent habit, plumped for a fatty heart, and that case was ticketed. Another lot of hearts are maligned because the first sound is weak, a perfectly worthless criterion, unless hedged round with all sorts of qualifications; and a still larger number because the pulse is small and feeble; and then there come all the multitudinous causes of irregularity of the heart, which in the absence of any definite disease are all liable to go into the same pot, and a pretty kettle of fish comes out of it all if we take the aggregate of results of misery that is produced. I cannot discuss this question very satisfactorily, because there are so many causes of irregularity; but I can say this, that no more common condition exists than the irregularity of the neurotic heart, and though we all know of it I do not think that its very frequent occurrence is as generally remembered as it ought to be. A great injustice is not unfrequently done to candidates for insurance in this way. A man goes up for examination and is nervous under it. His heart is unsteady, and very likely there may be some slight basic or apical systolic bruit as well, and he is warned not to pursue his proposal at the time, but to come again in so many months. What is the result? Naturally the rejected candidate receives a severe shock. Imagining himself sound, he finds there are suspicions about his most vulnerable part—his heart,—and off he goes to "another opinion" to know if there is any chance of sudden death, heart disease and sudden death being indissolubly bound together in the mind of the layman. Far be it from me to seem to be wanting to teach the medical officers of insurance societies their business; they probably know it far better than I, and, moreover, not being attached to any body of this sort, I am very much like the politician out of office, except that I am not trying to get in. But I will confess to having wished, as cases of this kind have come before me, that medical examinations for insurance could be conducted with a little more bilateral poise, for the refusal to grant a policy is really of more moment to the candidate than it is to the shareholders of the company; for I am of course only discussing cases that could add at the most an infinitesimal risk, and yet the one party does not receive a particle of consideration. But having said this, I will let it at once discover my weakness, for it opens up a most interesting question, whether the irregularities of neurotic origin may not in the end lead to some failure of the muscle, and so confirm the fitness of their rejection.
